This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

CYCLE AND
AUTOMOBILE TRADE JOURNAL

Vol. XII, No. 1. PHILADELPHIA AND NEW YORK JULY 1, 1907

June Edition, 20,377

18,253	Copies mailed.
5,500	Copies delivered to News Company.
795	Copies to Philadelphia and foreign under stamps.
20	Copies held in reserve.
24,568	
4,191	Back numbers sent out.
20,377	Total copies June edition.
	Of these
12,926	Were paid subscriptions.
5,500	Delivered to News Co.
18,426	
1,822	Returned by News Co., to June 22, 1907.
16,604	Net total paid.

We print on this page each month an exact statement of the number of copies printed and distributed of the preceding issue of "The Cycle and Automobile Trade Journal."

The bindery count of actual complete copies produced of the June issue was 20,377.

Of these, 26,810 pounds were mailed at pound rates, as shown by post office receipts. Each copy weighs 23½ ounces, representing 18,253 copies, and 4,191 copies of back numbers and copies returned by news companies are accounted for, in addition to the total for the month.

We will be pleased to verify the above figures at any time to any one interested.

Races at Reading, July 4th

Berkshire Automobile Racing Association has been formed in Reading, Pa., with O. Koller, of the Reading Automobile Company, president and secretary, and E. S. Youse, treasurer. This association has been formed for the purpose of promoting race meets, and on July 4th will hold a race meet at Shillington track. There will be ten events on the program.

On August 9 and 10 the United States Motor Racing Association will conduct a 24-hour race at Brighton Beach track, New York.

Coming Events

July 2—Grand Prix, Automobile Club of France.
July 4—Harrisburg Pa., Peter's Mountain Hill Climb, Motor Club of Harrisburg.
July 4—Race Meet, Houston (Texas) Automobile Club.
July 5-14—National Motor Car Show, Bergen, Norway.
July 10—Start of Fourth Annual Tour of the American Automobile Association, for the Glidden trophy; start at Cleveland, Ohio, and finish at New York on or about July 23.
July 13—Chicago Race Meet for the Entertainment of the Glidden Tourists, Chicago Automobile Club.
July 15-18—Ostend Week, Record Trials, Automobile Club of Belgium.
July 22—Ardennes Circuit (Belgium).
July 31—Leiderkerke Cup for Touring Cars, Ardennes Circuit (Belgium).
July 31-August 8th—Belgium Regularity Contest for Touring Cars, A. C., of Belgium.
August 1—Hill Climb, Algonquin Hill, Chicago Motor Club and Chicago Auto Trade Association.
Aug. 1-4—Providence, R. I., Federation of American Motor Cyclists, National Meet.
Aug. 1-7—Criterium of France, 1750 miles touring competition and 250 mile race for the press cup. (Exact dates to be fixed). A. C., of France.
August 5-10—Automobile Carnival (Races and Show), Atlantic City, N. J.
Aug. 8—International Relability Contest, Belgium.
Aug. 9-10—New York City Brighton Beach Track, 24-hour automobile race, U. S. Motor Racing Association.
Aug. 11-20—Auvergne Cup Competition, France.
Sep. 1—Italy, Brescia Circuit, Florio Cup, A. C., of Italy.
Sep. 2—Labor Day Hill Climb, Sport Hill, Bridgeport (Conn.) Automobile Club.
Sep 5—Cedar Lake Economy Run, Chicago Motor Club and Chicago Auto Trade Association.
Sep. 9—Commercial Vehicle Trials of English Royal, A. C.
Sep. 14— 95-mile road race, Albany Automobile Club, of Albany, N. Y.
Sep. 14-15—Mont Ventoux Hill-Climb.
Sep. 15—Semmering Hill-Climb.
Oct. 1-15—Contest of Electric Vehicles, Automobile Club, of France.
Oct. 6—Cup of L'Auto Maisons-Laffitte.
Oct. 19—St. Louis (Mo.) International Aerial Race for the Gordon-Bennett Prize.
Oct.20—Galion Hill-Climb.
Oct. 31-Nov. 7—A. L. A. A. M. Show, Madison Square Garden, N. Y.
Nov. 12-Dec. 1—Paris Show, Grand Palais and Place Des Invalides, A. C., of F.
Nov. 30-Dec. 7—Chicago National Automobile Show, S. A. Miles, Mgr., No. 7 E. 42nd St., N. Y. City.
Dec.14-21—Local Show, St. Louis, Mo., Auto Manufacturers' and Dealers' Association.
July 14, 1908—Aerial Race, Paris to London.

S. A. Miles, manager of the N. A. A. M., has been sending a last call to applicants for space in the Chicago shows—pleasure and commercial—both of which will be held November 30 to December 7, one in the First Regiment Armory and the other in the Seventh Regiment Armory. Space allotments are to be made July 1, and as usual the indications are that the applications for space will exceed the supply.

vill be held August 8, 9 and 10.

Atlantic City Automobile Carnival

An automobile carnival, including three ys' racing, a floral parade and a three ys' show, will be held at Atlantic City, J., the famous seaside resort, during the ek of August 5 to 10. The races will be ld on Monday and Tuesday, under the spices of the Atlantic City Automobile ub, on the beach at Ventnor, just south Atlantic City. The floral parade will take ce on Wednesday over a five-mile route asphalt streets, passing before a grand nd seating 5000 persons. The Show, ich will take place on the remaining three ys of the week, will be held on Young's ew Million Dollar Pier, the exhibition hall ving an unbroken floor space of 150 by feet. This is the first automobile show ld during the summer months, altho rail-y and street carmakers and others have ld shows at Atlantic City several times in past. During the month of August there fully 250,000 visitors in the city, includ-g prominent men from all parts of the untry. Applications for space should be nt to C. Wood Tatham, Boardwalk and uth Carolina avenue, Atlantic City, N. J.

American Society of Mechanical Engineers Meet

At the sessions of the recent meeting of American Society of Mechanical Engi-ers at Indianapolis, Ind., important ques-ns pertaining to automobile construction re discussed. The society for the first ne in its history has recognized the auto-bile as a legitimate subject for engineer-g study.

Ind., was laid on June 22. The guest honor was Vice President Charles W. F banks. E. H. Bundy made the opening dress, after which Mr. Fairbanks mad characteristic address. Speeches were a made by Charles S. Hornley and Mark Forkner. The main building will be feet by 310, the power house being 200 by

Glidden Tour Schedule with Additio Entries

The schedule for the fourth annual t for the Glidden trophy has been announc The tour will cover a total distance of 1, miles and take 15 days elapsed time. actual running time will be twelve days, others being spent for stopovers. The lo est day's run will be 174 miles and shortest 97.

As heretofore all cars will be prohibi from carrying signs or advertising ca but each car will be supplied with two p nants with the name of the car on then

The schedule is as follows:

	M
July 10, Cleveland to Toledo, Ohio	
July 11, Toledo to South Bend, Ind	
July 12, South Bend to Chicago, Ill	
July 13-14, spent in Chicago	
July 15, Chicago to South Bend	
July 16, South Bend to Indianapolis	
July 17, Indianapolis to Columbus, Ohio	
July 18, Columbus to Canton, Ohio	
July 19, Canton to Pittsburg, Pa	
July 20, Pittsburg to Bedford Springs, Pa	
July 21, spent at Bedford Springs	
July 22, Bedford Springs to Baltimore, Md

Three-Day Endurance Test of the New Jersey Automobile and Motor Club

The three days' endurance test of the New Jersey Automobile and Motor Club, held on May 30-31 and June 1, proved too easy to eliminate the up-to-date cars of today. Of the 26 contestants only 3 were obliged to drop out, and at least 12 came thru with perfect scores. In the touring car class there were 14 contestants for the William C. Shanley trophy. Fifty per cent. of the cars in this class obtained perfect scores.

Among the runabouts, 12 of which competed for the Angus Sinclair trophy, 5 finished with perfect scores. The circuit for the first day measured 121.9 miles, and included Schooley's Mountain, but with the exception of a few short stretches the roads were excellent. The second day's run of 154 miles from Newark to Atlantic City via Trenton, was very easy, the roads being fine, and the same was true for the 139.5 miles on the return to Newark via Thomas River, Freehold and New Brunswick. The total mileage was 415.4, and the schedule kept the pace well within the speed limits. The disposition to be made of the cups, which cannot well be divided among the numerous perfect score cars was not yet decided at the time of this writing.

A. L. A. M. Managers Meet

The semi-annual meeting of the Board of Managers of the Association of Licensed Automobile Manufacturers, was held June 4 in the association rooms, New York, all members of the association being present. The morning session was given over to a discussion of the litigation now pending against the manufacturers and dealers of unlicensed cars, suits of which were filed during the month of May.

The afternoon session was occupied with matters pertaining to the forthcoming show in Madison Square Garden. The show committee recommended to the Board the selection of the decoration scheme for the Garden offered by S. R. Ball. The Board unanimously sanctioned the selection of this scheme, and practical work on the decorations will begin at once.

Marcus I. Brock, assistant general manager of the association, who resigned from the show committee last year, was reappointed a member of the committee, to take the place of Carlton R. Mabley, who resigned. One of the features recommended by the show committee and adopted by the Board, was the elimination of any demonstrations at the show.

Owing to the number of applications for space from manufacturers of motorcycles, the recommendation by the show committee that an exhibit of motorcycles be given was approved. Space will be given and a complete exhibit of motorcycles be had in connection with a full line of commercial vehicles which have been promised by members of the association.

The question of good roads was also taken up and $5000 appropriated to be used at the discretion of a good roads committee, which will be appointed later. This committee will work in connection with the good roads committees of the National and other associations.

After the regular session of the Board the handbook committee, consisting of L. H. Kittredge, M. E. Metzger and Thomas Henderson held a meeting to discuss the 1908 handbook, which they hope to have ready by the time of the New York show in Madison Square Garden.

Connecticut Hill-Climb

With weather of the made-to-order sort, and Joe Tracy as a drawing card, the success of the Bridgeport Automobile Club's hill-climb, at Sport Hill, near Bridgeport, on Decoration Day, was assured. The course was on the Easton road, one mile in length, with a grade of from 8 to 10 per cent., and having several dangerous curves.

The fastest time of the day was made by Tracy and C. S. Bragg, in a tie. Time, 1.24 4-5. Summary:

CARS COSTING UNDER $1000.

Philadelphia, July 1st, 1907

Interchangeability of Auto Parts and the Low-Priced American Car

The improvement of the American-built automobile has been so rapid that it might be considered almost phenomenal. This sudden development is not alone in design, but in workmanship as well, rapid advances have been made.

The factors which have made possible this "Alladin"-like appearance of the almost perfect car are varied in the extreme, for as usual with the growth of most mechanical products, the prominent and tangible results are effected not only by such major factors as materials, design and workmanship, but just as surely only in a less degree by such minor influences as the circumstances and surroundings of the workmen. The American workmen as a class are without question in better circumstances and surrounded by more comforts than are the same class in Europe, and the Americans seem to be natural adapts in the handling of machine tools. They may not display the painstaking care of minute details shown in the hard work of many of the artisans of Europe, but give them intricate and complicated machines, and they are as a rule very competent to produce accurate and interchangeable parts.

Here we touch the "needle adjustment" of the entire automobile industry in this country "interchangeability." Without this one pertinent feature, the phenomenal growth of the manufacture of the American high-grade moderately-priced automobile could not have been possible. To produce comparatively low-priced, well-built machines with interchangeable parts requires highly specialized machines, and these have been developed to a marked degree of perfection, and are now so universally used that hand-made parts have practically been eliminated.

During the formative period, of course, very few parts were duplicates, and a large part of the work was hand-produced, and even at the present time there are still many more machines on the market containing hand-made parts than is good for the industry. Nevertheless, the American automobile manufacturers to-day doubtless excel all other nations in the production of small, medium-priced but accurately made automobiles. This fact is attested by the large number of such machines now being exported and these little cars with interchangeable parts have been made possible only by the use of accurate American machine tools, replete with ingenious labor and time saving devices.

Some of the French papers seemed to be considerably wrought up over the gold cup tour or so-called "American Invasion," but the real danger of an invasion lies in the growing popularity of the American small car in France, whose manufacturers are extremely weak in this type, the majority of their plants being equipt apparently exclusively for the production of large high-priced touring cars. The present outlook would indicate that the exclusive production of these very well made, but large and expensive touring cars, which unquestionably has given the French their high reputation as automobile builders is likely to prove, if the American manufacturers avail themselves of the present opportunity, a decided stumbling block in the way of their successfully supplying their home demand for well-built, medium and low-priced cars.

Department Store Cut-Price Methods

The automobile business thus far has been fortunate enough to escape the cut-price methods which have in so many other industries proved disastrous. The prices of automobiles and accessories have, by many, been considered unnecessarily high, but when the fact is considered that the business is to a large extent experimental, that new equipments were required, and even new types of machines designed for the work, and that the models rapidly changed, doing away with the possibility of using old machines and parts, it will be seen that the margin of profit is not as large as might be imagined, in fact, it is generally known that in proportion to the amount invested, comparatively few automobile manufacturers have become independently wealthy.

There will naturally be, as the industry assumes a fixt form, and the models reach a standard design, a time when the cost of production will be reduced, and prices will probably be somewhat lowered. But already the pernicious effects of the sale of accessories and parts as leaders, particularly by

Hosted by Google

department stores and so-called cut-price jobbers, are making themselves felt, and if continued, will ultimately work considerable damage not only to the legitimate dealers, but to the purchasers as well, as the usual result of the continuance of such conditions is a general deterioration in the quality of the goods.

It would seem that manufacturers and others would realize the importance of the situation sufficiently to refrain from selling large quantities of accessories and parts to department houses at a very small margin, simply for the sake of small present profits. It must be clear to them that the practice of these retailers of selling popular accessories at extremely low margins of profit or even advertising at cut rates certain articles which it is found when inquired for are not even in stock, something just as good usually being offered the unsuspecting customer, will eventually make it impossible for the dealers to remain in the field. An absolute refusal to supply goods to such firms seems to be the only means of protecting the legitimate trade from being undersold.

Most manufacturers are perfectly willing to protect dealers who act as their agents, but these manufacturers are powerless to cope with such a situation when the dealers themselves do not co-operate with them, and it is hoped that the urgency of the situation will be realized by both the dealer and the manufacturer. The conditions here pointed out show clearly the growing necessity for the formation of some kind of manufacturers' organization, which will be in a position to put a stop to such demoralizing practices.

Endurance Contests

The automobile manufacturers seem to be waking up to the fact that speed and endurance contests between stock cars are much more valuable and mean more to the permanent advancement of the industry than any contest of freak cars can possibly mean.

At last we are having real contests of actual stock cars, and the results cannot help but be beneficial to the entire automobile interests if the contests are scientifically conducted and entered into by all the manufacturers.

Beyond question many points about steering gears, tires, frames, carburetors, etc., have been learned in the past from contests of even freak machines, how much more, then, is brought out by a contest of regular stock models on ordinary roads.

The recent endurance run from New York to Albany proved the mechanical capabilities of American cars, and the remarkable showing of the cars entered in the A. C. A. "sealed bonnet" contest has opened the eyes not only of our own country, but of all Europe to the fact that the American automobile is no longer a thing of experiment, but a sound mechanical unit practically fool proof and under any ordinary conditions capable of running hundreds of miles with absolutely no repairs, adjustments or even attention. Reliability! the one feature which has so long been sought and so few years ago the lack of which has given rise to so many jests about the under side of the machines has at last been demonstrated beyond a shadow of a doubt to be possest not alone by the high-priced palatially-equipt touring car, but also by the small and inexpensive, but well-built American machines.

This contest was a surprise not only to the general public, but to the dealers, manufacturers and even those most familiar with the up-to-date car. It has shown that at any reasonable speed such as sane men care to drive on ordinary roads over 80 per cent. of the cars entered are capable of covering 150 miles a day for four days, and even longer without so much as cleaning a spark plug.

There are, of course, many things which can be criticised, and it is to be regretted that some of our manufacturers of so-called high-grade cars do not enter them in such competitions, and it is well understood that such a refusal always lays the manufacturer open to the remarks of those who may justly or unjustly believe that such a course is prompted by cowardice. It was a noticeable fact that only two makes of foreign cars entered the A. C. A. contest, and it is not to be wondered at if some attributed this to the reluctance of foreign makers to enter into competition over our, at best, poor roads.

Undoubtedly every car in the sealed bonnet contest will be taken down and closely examined, and it is much to be regretted that the club did not go a step further and have this done officially under the supervision of a competent corps of engineers, and then give penalizations according to the findings of such a body. To have known accurately the amount of gasoline and oil used by each contestant would also under the conditions have been a simple matter and would doubtless have thrown many side lights on the actual performance of the competing cars, and it is herewith suggested that in the future such contests be not shorn of part of the good they can accomplish, but be carried out to a logical and extremely beneficial completion by every reasonable means.

An international exposition of automobiles, motorcycles and motor boats will be held at Copenhagen, Denmark, Sept. 29 to Oct. 7, under the joint auspices of the Danish Automobile Club and the Society of Motor Manufacturers and Agents. An elaborate booklet, printed in English, has been issued to advertise the exposition in English speaking countries and copies can be obtained by addressing L. Bendixen, Copenhagen, Denmark.

The proposed 5000-mile tire trials in England and France have been postponed until the spring of 1908.

Hosted by Google

Saturday, June 22, witnessed the finish of robably the most uneventful yet most imortant automobile contest ever held in merica. The four-day "sealed bonnet" ontest proved a great surprise to everyody, as out of the 47 participants 41 finished

Cars in Sealed Bonnet Contest in front of the club house before the start.

he entire 600 miles on schedule time and vith perfect scores, not even the slightest djustment having been made. Not only lid the cars run perfectly but at the close of the fourth day's run, as the machines drove into the control at Newtown on the Long Island course, all the motors seemed o be purring as sweetly as could be desired by the most fastidious, and it is the firm conviction of the writer that a large part of the cars could easily have contin under the existing favorable conditions many days to come, without even so m as touching a spark plug, or tightenin nut. The committee in charge, consis of Robert Lee Morrell, chairman; John Hill, A. L. Ricker, S. M. Butler and Whiting, were evidently not prepared any such showing of cars at the finish were probably counting on having bad weather, which would undoub have eliminated some, or certainly a cup would not have been offered to car finishing with a perfect score. It now as tho the A. C. A. will have to s about 41 silver cups. Certificates, st

Hosted by Google

Cars at Maplewood Inn,

distance completed successfully under rules will be given to those who did not h. Much to the surprise of every one, weather was practically ideal all four s, the blinding rays of the sun being htly obscured by light clouds—one can- help speculating upon what the results ld have been had the cars encountered roads as were met with in the recent urance run to Albany.

ccording to the schedule, all the cars, ept the two high-powered runabouts in s A, had a minimum of 7 hours 45 min- and a maximum of 8 hours 15 minutes hich to complete the 150 miles each day, n average of about 17 miles an hour required. One hour for lunch and taken in repairing tires was not count- n the running time. The Class A run- ts, two of which were entered, the six- der Darracq, driven by S. B. Stevens, the 40 H. P. Matheson, of R. G. Kel- were required to cover 170 miles each but were given 9 hours 15 minutes and urs 45 minutes as minimum and maxi- time allowance, so it will be seen the pace was very moderate, and as in open country and on good stretches of ro a higher speed was indulged in there w necessarily considerable loafing thru t villages and speed-restricted neighbo hoods. At all such places a man waving green flag gave notice to the drivers, and second man with a green flag indicat that that particular trap had been passe

Perhaps to the moderate pace can credited the almost remarkable absence tire troubles, as only about five cars we detained for this cause thruout the enti four days. The inhabitants of Long Islar and the occupants of passing touring ca were much surprised at the sight of many high-powered machines evidently a contest but yet driving at so moderate rate of speed. In Long Island it seems ne to impossible to make the people, who a used to the Vanderbilt Cup races, unde stand that there can be such a thing as contest with automobiles without racin and one old farmer very tritely voiced th feelings of many an observer when he re marked, "somehow, these cars don't see to be trying." In truth, this remark wa very typical of the whole run. No on

Maxwell Runabout, the smallest and lowest-priced machine in the contest, on the road, near Darien.

med to be very strenuous, the cars roll- along easily and the fact that the tool xes were sealed apparently caused no rry, all the drivers seeming to have the nost confidence that their engines would ep right on running without attention, l the fact that the engines did, speaks umes for the mechanical perfection of mechanism of the up-to-date machine. ry few cars emitted more than a slight ish haze from the exhaust, showing that lubricators were also working properly. attempt seemed to be made by the op- tors to favor the engines by stopping m when waiting at controls or outside of club house, and this was true also of the -cooled cars, the engines of which were en left running.

DETAILS OF THE FIRST DAY'S RUN.

'he course for the first and fourth day s the same, being for a large part over famous oiled roads of the Vanderbilt ırse, the route beginning officially at wtown, the first control, where the cars eived their official starting time. The s left the club house promptly at 8 lock, all getting away within a space of minutes. An amusing incident occurred the start when it came time for a car bearing the number 23 to be sent aw the driver had some slight difficulty starting, and grew very red ,and somew exasperated as all the small urchins yel "skiddoo," "23 for yours," etc. There w no car numbered 13, for altho we are su posed to be living in the enlightened tw tieth century, it is nevertheless true th many still cling to the old superstition regard to this much-abused number.

From Newtown the cars were sent aw at one minute intervals, the route bei over the Queen's Road to the well-kno Jericho Turnpike, turning at Krug's C ners over to the Hempstead Turnpike, th Bull's Head Corners, passing Jerich Hicksville and Amityville. At the la named point the club's men with gre flags were stationed to notify the drivers go slowly, as the speed regulations rigidly enforced in this village. The tu ing point, markt by a yellow flag with gre letters, was nine-tenths of a mile beyo Patchogue; at the latter place most of cars stopped and their occupants rega themselves with sandwiches, which for most part were eaten while in the cars visiting a neighbor's machine, while son who preferred to finish earlier, ate lunch

Cars at Woodmont, third day.

e car on the return trip, which was a re-
rsal of the outward route.

At all the dangerous grade crossings flag-
en, who displayed the usual white or red
gs, were stationed by the club. Some of
e roads had recently been oiled, which
pt down the dust and made it possible to
joy to the full the delightful scenery.
owever, there was a tendency the first day
r the cars to bunch up, which made it
mewhat dustier than over the same
urse on the fourth day, when, except for
occasional bunching of the cars for a
tle brush, the contestants were content
jog along at a comfortable speed just out
reach of the preceding car's dust.

All returned within schedule time, the
st to reach the club house being the Olds
unabout, which had also been the first to
art. Only three of the cars had tire trou-
es. The Maxwell runabout and Stevens
arracq were slightly delayed and the Glide
rived with a flat front tire which had
one down just before reaching the club.

After the odometer readings and time of
ch car were reported to the committee by
e official observer, the seals of each car
were inspected and "gas" and oil taken
and the cars were then run onto one of
spacious garage floors and left over n
under the committee's supervision.
Mathison cars were allowed to raise t
hoods and oil the overhead cam shafts.
driver inquired if he could put a little
on the magneto, but this privilege was
granted, and the thought flashed thru
mind of the writer as to what the op
tor's feelings would be if by chance
should get a glimpse of some part wh
was working loose, knowing that he co
not apply the "ounce of prevention,"
that in this contest there would be
"pound of cure."

The six-cylinder Darracq, driven by S
Stevens, was reported as out of the
ning, but came in later well within the t
allowed, having been delayed by slight
troubles. At the end of this first day th
was much surprise that all the cars finis
the predictions being many that the t
and fourth days would see a large num
drop out, but it seems the American car
better piece of mechanism than even th
best acquainted with it were aware.

Digitized by Google

Filling the tanks, the only care the cars received.

THE SECOND DAY'S RUN.

The second day's run was somewhat ore difficult, as the course lay over much llier roads to Danbury, Conn., and return y way of Bedford, Kensico, White Plains nd Hartsdale to the starting control at uber's Hotel, on Jerome avenue. Forty-x cars started on the second day, being l but No. 28, a Stoddard-Dayton runabout, hich was disqualified over night by the ommittee for having placed a nut on the eering wheel the previous day. To have ontinued without the nut would have been angerous. A protest was also entered gainst the 50 H. P. Pope-Toledo, driven y Joe Judge, for using a pair of pliers on e foot throttle.

At Newcastle Corners the men with reen flags were met and the pace was ackened; however, F. Offenhauser, driver the Maxwell touring car, and F. Cimiotti, iver of a 24 H. P. Mora runabout, found emselves confronting a rope stretched

mines an hour, but the Judge fined each $10. F. Offenhauser paid the under protest and gave notice that he tended to appeal the case, but Cimiotti, was evidently a good talker, persuaded Judge to remit his fine. Both cars ceeded, and the observers deducted time from the running time.

The first car to be eliminated by bre ing the seals on the bonnet was the 45 P. Columbia, with electrical transmiss driven by C. F. Barrett. An inlet v spring broke and after running a while three cylinders it was decided to stop put in a new spring, which, of course, them out of the contest, altho they con ued the run.

There were many sharp S turns, but route in every case was clearly defined large yellow arrow heads nailed to fence telegraph poles, and no difficulty was perienced in following the course. A passing Salem Center, the cars followed north shore of Titus Reservoir to the tu ing point, and then retraced their route about 3½ miles before turning off to No Salem. The portion of the road retra was very narrow, and about five inches d with fine dust, which, continually stir up by the passing and repassing cars, almost suffocating, and the drivers w compelled to run very slowly, as it was possible to see any distance ahead.

On our return trip the Glide touring was noted at Peach Lake, 64 miles from starting point, hung up by trouble wit tire rim. The time was deducted, howe and the committee classed the delay as trouble. The car did not reach the until after 11 that night.

THE THIRD DAY'S RUN.

The conditions for the third day's over the Boston Post Road to Bridgep Milford, Woodmont and return, were

Hosted by Google

Cars finishing fourth day's run, at the Newtown Central.

ost ideal, as a slight rain the previous ght had laid the dust, and the sky was t clouded enough to ameliorate the heat the sun. However, the roads are not of e best and cannot be compared to those Long Island. The official time was taken the start, as on the second day's run, the control at Huber's Hotel on Jerome enue.

Forty-five cars started, as so far only two rs had been eliminated. As on the preous day, the Glide had tire troubles and l not return until late. The De Luxe d ignition troubles near Barstow, and had break a seal in order to make adjustents, but continued the run as a nontestant.

THE LAST DAY'S RUN.

On the fourth day 44 started the run, beg over the first day's course. The weather ntinued ideal and all seemed to enjoy to e full the beautiful roads and scenery. ear Hicksville the official car was met d we were informed that word had been ceived that the six-cylinder Darracq runout, driven by S. B. Stevens, had stopt th engine troubles and had to break a l.

At one point a group of children were hted playing in the road, and it would pear to the uninitiated as tho they might t get out of the way in time, but at the st "honk" of the horn, these children, o are used to the Vanderbilt Cup races, ed up on the curb with the precision of military company doing a wheel into line, d saluted us with cheers as we went by. erywhere on the Island the friendly feel- of the people toward the automobile is making considerable noise for the last t days, was seen on Roslyn Hill apparen out of the running.

On the whole, the performance of cars was remarkable and proves conc sively the fact that the automobile to- is practically fool proof and a perfec piece of mechanism. The competing c were without exception stock models, a some of them had already done many th sands of miles.

The contest was well planned and s tematically conducted. The bad turns w all indicated on the route cards, and all d gerous grade crossings were well guard

Fast Time at Cleveland Hill Climb

The first annual hill climb of the Clev land Automobile Club, held on Stucky H 20 miles east of Cleveland, on June proved a success. Walter White, driving white steamer, covered the three-fifths a mile up the 20 per cent. grade in 47 seconds or at the rate of a little more th 53 miles per hour. The Mora car ent ed in the contest was followed by hard lu it having covered the course with two f tires, only losing by 10 seconds.

Endurance Run of the New York Motor Club a Mud Contest

Probably the most strenuous endurance contest ever held in this country was the 208.1-mile test of the New York Motor Club. The course led thru Tarrytown, Cold Springs, Poughkeepsie, Amenia, Great Barrington, Pittsfield, Chatham, and finished at Albany. This is certainly the longest route ever laid out for a one-day endurance contest over public roads, and to add to the rigors of the situation, the roads were wet and in fearful condition.

The start was made from Columbus Circle, New York City, early Thursday morning, 27 of the 29 entrants being sent off at 1 minute intervals, only two failing to make an appearance. All of the cars arrived at the first control without penalization, at the second station four had marks against them, and the perfect scores of eight more were spoiled by the time Poughkeepsie, the third station, was reached. At Amenia, the half-way station, 102.2 miles, nine cars still had perfect scores, but by the time Chatham, 183.9 miles, was reached every car had been penalized.

The Corbin, driven by James Corbett, finished with the best score for touring cars, having only nine points against it, but was disqualified on protest of E. L. De Camp, it being claimed that only three instead of four passengers were carried by it from Great Barrington to Albany. The committee declared the Corbin ineligible and the trophy in this class was awarded to the Lozier, driven by H. Michener, who had the second best score. The runabout class trophy was won by C. B. Warren in a Haynes.

The contest was well conducted, but there was a fatal accident which cast a gloom over the whole affair. James Swan was driving his Corbin runabout at good speed in making up lost time, and in crossing a trolley track at the foot of a hill near Albany, the automobile was struck by a trolley car running at top speed. The machine was completely wrecked. Clarence McKenzie, observer, who occupied the rumble seat, was instantly killed. Warren E. Mosher, who occupied the front seat, was badly injured, but Swan was only slightly bruised.

The following is the order of penalization of the 18 finishing cars and their mechanical score:

Car.	Driver.	Penalized.	Mech. Score.
Corbin,	Jas. Corbett	9	Perfect
Lozier,	H. Michener	18	Perfect
Haynes,	H. M. Vanderbilt	20	Perfect
Welch,	E. L. De Camp	24	
Reo,	R. L. Lockwood	48	
Stoddard-Dayton,	R. L. Newton	50	Perfect
Berliet,	P. J. Johnson	79	Perfect
Mitchell,	E. W. Hudson	103	
Premier,	C. O. Singer	106	
Continental,	C. S. Johnson	182	Perfect
Pope-Hartford,	Phil Hines	131	Perfect
Frayer-Miller,	H. H. Knepper	300	Perfect

The Long Island Automobile Club's Endurance Run

The two days' run of the Long Island A. C. proved that harder tasks must be set the modern automobile if it is not intended to present prizes to all the entrants. Out of the 20 starters in the run of 139 miles the first day and 154.6 miles the second day, 18 finished at the Brooklyn club house before their scheduled time limit.

There were ten cars that covered the 193.6 miles without stops except at controls, and without attention other than filling the oil and gasoline tanks.

The results are as follows:

CLASS A MACHINES COSTING UP TO $1500.

Cadillac, J. D. Ronk, clean score, tied.
Cadillac, J. D. Rouk, clean score, tied.
Holsman lost nine minutes on carbureter adjustments.

CLASS B, MACHINES COSTING FROM $1500 TO $3000.

Columbia, E. H. Barnum, clean score, tied.
Oldsmobile, R. E. Pardee, clean score, tied.
Pope-Hartford, C. G. Arnold, clean score, tied.
Queen, carbureter adjustments; Thomas, loose connecting rod; Franklin, broken fan; Haynes, disabled; Aerocar, damaged in avoiding a collision with a carriage.

CLASS C, MACHINES COSTING $3000 AND UPWARDS.

Matheson, R. G. Kelsey, clean score, tied.
Packard, S. H. Burns, clean score, tied.
Pope-Toledo, A. N. Wilcox, clean score, tied.
Pierce Arrow, A. B. Coles, clean score, tied.
Winton, C. A. Carlson, clean score, tied.
De Luxe and Dolson had carburetor adjustments; Welch broke pin in oiler.

It was finally decided to run a supplementary endurance run for the tied cars, but this simply resulted in reducing the number from 10 to 7, and ties still exist as follows: Class A, Cadillac and Maxwell; Class B, Columbia and Pope-Hartford; Class C, Winton, Pierce and Packard. It is probable the names of the tied drivers will be engraved on the different trophies, which will be held by the clubs, and certificates awarded to the cars.

It is a noteworthy fact that in this second trial of 200 miles all of the resulting seven that tied reached all the controls on time and did not make a single replacement, and even the three that lost their perfect score record were penalized owing to trifling mishaps which in no way reflected on the quality of the cars.

Aluminum Alloys

Syracuse, N. Y., June 11, 1907.

Referring to your June issue, page 65, the article under the head of "Aluminum Castings."

There is a great deal of information in this article which is of value, and there is considerable which is worse than useless because it is false. But before we attempt to correct any of the statements, we wish to say we believe that Mr. Dolnar never intended to write anything which was not correct, but feel that he has been led into this by reason of using statements given to him from sources which would naturally be considered correct, but unfortunately where there are "axes to grind."

The part of the article to which we take exception commences with the second paragraph in reference to Zinc Alloys as compared with Copper Alloys. The impression that Mr. Dolnar gives is that aluminum-zinc alloys are inferior to copper alloys as far as resistance to vibration is concerned, although he admits that zinc alloys are the strongest.

Our position in the automobile casting field, namely, that of being the largest producers of zinc-aluminum castings in the business, makes it necessary for us to take some action to correct the impression which is being so industriously circulated by some of "our friends, the enemy," that zinc alloys are inferior to copper alloys.

The aluminum foundry business at the present time is divided into two camps, on the one hand those who use the Aluminum Company of America's No. 12 alloy, which was formerly known as nickel-aluminum, and which is 93 per cent. aluminum and 7 per cent. copper, and those who use zinc-aluminum alloys of various kinds, running from the Aluminum Company of America's No. 31, which contains 82 per cent. aluminum, 14 per cent. zinc, the balance copper and manganese, to those who use an alloy of nothing but zinc and aluminum. There is also a dividing line among the automobile manufacturers along the same lines.

There is a vast difference between the positions taken by the two foundry factions. The zinc-aluminum people concede that No. 12 is a good alloy, but claim that the zinc-aluminum alloy is better. On the other hand, the No. 12 foundry people take the stand that there is absolutely nothing to it but No. 12; that all the rest of the foundrymen do not know what they are doing; that their metal is no good, never was and never can be made good.

Now let us look into this proposition. No. 12 has an average tensile strength of about 16,000 pounds per square inch, and none of the samples we have submitted for tests have ever shown any elastic limit. The gravity of this metal is about 2.87.

No. 31 alloy has an average tensile strength of about 30,000 pounds, with no elastic limit and with a gravity of about 3.05. These are the two standard alloys produced by the Aluminum Company of America and sold generally. So far as we know, neither of these alloys, when properly handled, have ever given any trouble.

However, we were not content to sit down and take the results of other people's experiments and say that was all that could be done with aluminum. So we started out to develop, for the benefit of ourselves and our customers, a better mixture than any one had produced.

We experimented along the lines of the use of copper and aluminum, zinc and aluminum, manganese and aluminum, and a combination of same. We are now experimenting with other metals which we do not yet feel disposed to announce. The results of these tests showed us very conclusively that in order to get the best results there was only one thing to use—ZINC.

We therefore began to develop a system of foundry practice which would enable us to get the benefit of all the strength of this alloy, and the results have been very, very satisfactory.

We have arrived at a point where we can produce an alloy of zinc and aluminum, with a tensile strength of 20,000 pounds, an elastic limit of 15,000 pounds per square inch, and a gravity of 2.95. We have another zinc-aluminum alloy having a tensile strength of over 26,000 pounds, and an elastic limit of 22,000 pounds per square inch, with a gravity of 3.00.

These results were all right as far as they went, and there was no question but what we had the best material on the market, but still there was this continual talk about the crystalization of zinc-aluminum alloys, and while we did not think there was anything to it, at the same time we considered it wise to make sure of the facts, so we had tests made and were able to demonstrate that zinc-aluminum alloys are infinitively superior to No. 12, as far as resistance to vibration is concerned.

For instance, the E. R. Thomas Motor Company, Buffalo, New York, raised this question of crystallization. They have an endurance testing machine at their plant, and we submitted to them a sample of our zinc-aluminum alloy and one of No. 12, both bars made under identically the same conditions. These bars were turned down to ½-inch diameter at the ends, which were 4½ inches from the ends of the grip. On this ½-inch diameter bar a 25-pound weight was suspended at each end. The machine was started running at 1200 revolutions per minute. The results, taken at the first break in each instance, were: The zinc-aluminum alloy ran 1,016,700 revolutions; the No. 12 alloy ran 214,000 revolutions, and a sample bar, alloy unknown,

Hosted by Google

submitted by a competitor, who probably does the most talking about the crystallization of zinc alloys, ran 100 revolutions.

The H. H. Franklin Manufacturing Company, of Syracuse, N. Y., have also made some very interesting tests along the lines of crystallization. Their apparatus is entirely different from the E. R. Thomas Company's, or the Henry Souther machines, in that theirs is an impact machine—that is, the aluminum is subjected to shocks similar to those actually received in automobile service. The Franklin people have found that No. 31 alloy will stand before breaking ten times as much vibration as No. 12. They are now testing our alloy under the same conditions, but the results are not yet at hand. They have tested our alloy on their endurance machine under the same conditions as the E. R. Thomas Company, and obtained about 900,000 revolutions. They have not tested No. 12 on their endurance machine.

We also sent sample bars to Mr. Henry Souther, of the Henry Souther Engineering Company, of Hartford, Conn., and requested him to make an endurance test, and inasmuch as we submitted the sample bar of No. 12 we asked him to make an analysis of both mixtures.

Under date of June 5th, he reports as follows:

"Syracuse Aluminum and Bronze Co.,
"Syracuse, N. Y.

"Gentlemen: Referring to your letter of May 18, the test specimens you sent for our endurance machine show the following results:

ANALYSIS.

37,262	7,800	Endurance	Specimen.	1,550,400	1,618,300

"Referring to the above results: To properly understand them, it must be understood that the load was exactly the same in both cases—30 pounds—and that it produced a fibre stress of 10,600 pounds per square inch, and a deflection of .06 inch on a .500-inch diameter specimen over a distance of 4.50 inches—that is, the load was applied at a distance of 4.50 inches from the support.

"It is apparent that the alloy containing zinc has double the endurance of the one containing copper. I will further state that these are most excellent results for aluminum alloys, as compared with others tested by us.

"Very respectfully,
"THE HENRY SOUTHER ENG. CO.,
"(Signed) Henry Souther."

The sample 37,261 is No. 12 alloy, received from the Aluminum Company of America. Sample 37,262 is our own alloy, and you will note that it stood nearly three times as much as No. 12, and also that the load in this instance was five pounds heavier than that used by the E. R. Thomas Company or the H. H. Franklin Company.

We are also in receipt of a letter from Mr. Souther in which he states that he has reported to the A. L. A. M. that zinc alloys are decidedly better than No. 12.

We think the above submitted facts show, without a question of doubt, that zinc alloys are better than No. 12, and that our own alloy is way beyond anything heretofore produced for the reason that in addition to obtaining a metal with a very low specific gravity we have succeeded in raising the tensile strength to a considerable degree. Further that we are able to produce a guaranteed elastic limit nearly equal to the tensile strength of No. 12, which is a very great advantage.

We do not know of anything we can add to the above, and we feel certain that if this information is placed before the automobile manufacturers of the country, who are, without exception, looking for something better all the time, it will dispose of the crystallization argument. This being disposed of, and with the additional tensile strength and the elastic limit shown by the zinc-aluminum alloys, the No. 12 alloy will soon be a matter of the past for automobile use.

Yours very truly,

SYRACUSE ALUMINUM & B. CO.
(Signed), Chas. L. Ackerson, Mgr.

[The information obtained from the Allyne Foundries was correctly given. It is also true, as claimed in this letter, that aluminum-zinc alloys have their users who prefer them, and that some large makers of motor cars who have used zinc alloy have abandoned it. The question as to whether zinc or copper alloys are the more suitable for motor car castings is as yet not decisively answered. There is no test for motor-car materials so convincing as that of actual work on the road, and nothing else will finally decide what shall be used.—Hugh Dolnar.]

Oldsmobile Stars at Readville

The races at Readville race track, Boston, Mass. on May 30, were witnessed by a large crowd. The Oldsmobile carried off the honors in both the 50 and 100-mile events in which a number of cars were entered. The first event was for 100 miles, in which the following cars started: 24-H. P. Dragon, 30-H. P. Stearns, 35-H. P. Oldsmobile, 20-H. P. Jackson, 30-H. P. Moon, 35-H. P. Grout, 50-H. P. Frayer-Miller, 30-H. P. Cadillac.

In the 50-mile event the starters were Royal Tourist, Jackson, American, Knox, Logan, Grout, Corbin, Oldsmobile, Dragon and Stanley Steamer.

The summaries follow:

100-mile event—Oldsmobile, 2.10.30; Cadillac, 2.16.35 1-5; Frayer-Miller, 2.38.16 1-5; Dragon, fourth, and Stearns, fifth.

50-mile event—Oldsmobile, 1.03.24; American, 1.04.45 1-5, and Royal Tourist. 1.05.55 1-5.

The German American Social Club, of Cleveland, O., changed its name and purpose at their annual meeting and will hereafter be known as the Country Auto Club.

Trade Changes and Removals

American Lamp Company of Detroit, Mich., recently increased its capital stock to $50,000.

Broadway Auto Co., of Somerville, Mass., has been succeeded by The Boulevard Auto Co., of that city.

Bellknap Motor Co. of Detroit, now known as the Michigan Steam Motor Company, has recently located in their new factory at Pontiac, Mich.

Brown Auto Top Company of Philadelphia, Pa., has recently removed from 1327 Buttonwood street, to 437-439 N. Broad street.

Buick Motor Co., Flint, Mich., has absorbed the Whitney Motor Car Co., of Jackson, and the Janney Motor Car Co. of Flint.

Dodd Motor Co., The, heretofore located at Grinnell, Iowa, has reorganized and leased a building at Third and Vine streets, Des Moines, where the manufacture of its motor will be continued.

Ideal Plating Company, 3 Appleton street, Boston, Mass., have been succeeded by the Ideal Plating Co., Inc.

Jeffery Co.'s, Thos. B., Chicago branch will be moved to 1462-4 Michigan ave.

Kimball, E. T. Company, Motor Mart, Boston, has been purchased by the Corbin Motor Vehicle Corporation, who will continue this agency as the Corbin Car Company of Boston.

Logan Construction Co., of Chillicothe, O., has increased its capital stock to $250,000.

Mitchell Motor Company, of New York, has moved to new quarters at 1876 Broadway, corner of Sixty-second street.

Muller Porous Plate Accumulator Co., The, 205 West 41st street, New York, N. Y., have been succeeded by Albert Muller.

New York-Broadway Rubber Tire Company, 1186 Bedford avenue, Brooklyn, N. Y., have been succeeded by the Martin-Evans Company.

Nicholsburg, H., Mfg. Co., 68 Dey street, New York, have been succeeded by the J. W. Fiske Iron Works.

Splitdorf, C. F., manufacturers of electrical specialties, have removed their factory from 17-27 Vandewater street, to 261-265 Walton avenue, corner 138th street, Bronx, New York.

Shearer Automobile Co., S. C., 1650-54 Glenarm street, Denver, Col., garage business succeeded by Michaelis-Middlekauff Automobile Co.

Submerged Exhaust Co., 149 Water street, Newburyport, Mass., have been succeeded by the American Submerged Exhaust Company.

Schultz, Co., G. J., of Yonkers, N. Y., manufacturers of spark plugs, have been succeeded by Willyoung Appliance Co., of that city.

Turner & Fish Company, of Chicago, Ill., have changed their style to Indestructible Steel Wheel Company, and established new offices at 1303 Michigan avenue.

Wolverine Motor Company recently removed from Grand Rapids, Mich., to Bridgeport, Conn.

Williams Electric Vehicle Company's plant on East 55th street, Cleveland, O., has been purchased by John Byrider, of Akron. The company will be known as the Byrider Electric Auto Company.

Fires, Judgments and Failures

Anderson Automobile Co., Aurora, Ill., a copartnership has been dissolved.

Back Bay Garage, Boston, Mass., destroyed by fire on June 17.

Defender Cycle Company, West 125th street, New York City, on May 25, damaged by fire.

Duquesne Construction Co., Jamestown, N. Y., defunct; creditors will receive 10 per cent. dividend.

Eisenhuth Horseless Vehicle Co., Middletown, Conn., receiver in bankruptcy, George T. Scull, has filed his account.

Franklin Garage, 347 Franklin street, Buffalo, N. Y., damaged by fire to the extent of several hundred dollars.

Fay, Owen H., garage at 243 Michigan avenue, slightly damaged by fire.

Jones, T. W. Motor Car and Storage Warehouse Company, 428 Twenty-ninth street, Chicago, Ill., on night of May 30, was damaged by fire to the extent of $100,000.

Motor Components Manufacturing Company's property sold by R. R. McCutchen, receiver, to F. E. Goodwin, for $2,555.61.

Mercedes Importing Co., and the Pennant Automobile Company, at 1459 Michigan avenue, Chicago, damaged by fire on May 20.

Newark Motor Car Co., 126 Fourteenth street, Newark, N. J., damaged by fire caused by the explosion of gasoline. Damaged aggregates about $15,000.

National Oil Tank Company, of Dayton, Ohio, suit for infringement of patent has been entered by S. F. Bowser & Co., of Fort Wayne, Ind.

Polson's, William F., automobile garage, at 22-24 W. Utica street, Buffalo, N. Y., burned on May 20.

Paxson Motor Co., 911-913 Huron road, S. E., Cleveland, Ohio, practically destroyed by fire on May 21.

Skinner, Kenneth A., 179 Clarendon street, Boston, Mass., damaged by fire on June 18.

Stamford Motor Company's factory, Stamford, Conn., damaged by fire. Estimated damage to machinery and building, $10,000.

Shaw, Walden W., automobile plant, 1532 Michigan avenue, Chicago, damaged to the extent of $70,000.

Schraeder's, Charles, garage, 2534 N. Broad street, Philadelphia, Pa., damaged by fire, to the extent of $1500.

Studebaker Bros., San Francisco, Cal., wagon, carriage and automobile store, destroyed by fire on June 10.

Union Automobile Co.'s garage, 521 to 525 Homewood avenue, Homewood, Beaver county, Pa., destroyed by fire. Loss will run well toward $30,000.

Willard Co., H. J., of Portland, Me., dealer, has been petitioned in involuntary bankruptcy.

Legislation

CALIFORNIA.

Autoists have been barred from the Yosemite Valley.

NEW YORK.

Buffalo.—The corporation counsel interpreting that city's new automobile ordinance, holds that cars sent out by manufacturers to prospective purchasers on approval are not subject to taxation and that manufacturers have the right to shift their registration numbers around from one car to another, paying a tax only for the car carrying the number.

OHIO.

Toledo.—Council has reduced the speed limit to ten miles per hour and have organized a motor cycle police corps.

WASHINGTON.

Centralia.—Council has passed an ordinance regulating the speed of automobiles and motor cycles. The speed limit is eight miles per hour and must be reduced to four per hour when passing other vehicles.

Warner Instrument Co. Showing-up Speed Laws

The Warner Instrument Company, of Beloit, Wis., has made numerous tests in New York and Philadelphia under widely varying conditions for the purpose of demonstrating the absurdity of the existing laws regulating the speed of automobiles and other vehicles. The tests were made with an automobile, on the back of which is mounted a monster Auto Meter, standing at least 10 feet high and with the figures on the dial about 12 inches in heighth. The car was run thru the streets at the speed limit of 10 miles per hour, with the meter registering the exact speed and showing to the public the ridiculousness of the 10-mile-an-hour speed law and also that horse-drawn vehicles, trolley cars and other vehicles were exceeding the speed limit in passing the test car. Further tests will be made in other cities thruout the country for the same purpose.

Exports Still on the Increase

During the month of April, 1907, the exports of American automobiles and parts reached $686,144, as against $408,333 for April, 1906, which shows an increase of $277,811. The report also shows an increase of $140,797 over that of March, 1907.

	April.	
Exported to—	1906.	1907.
United Kingdom	$74,746	$174,277
France	31,375	81,230

Valveless 2-Cycle

As Usual—
Something Unusual

Only 3 seconds variation per mile in a race of 50 miles.

"What!" you'll say, "only 3 seconds in 50 miles?" Yes indeed—and better than that—the two-cycle **Elmore** won the event hands down, beating a number of cars of much greater horse-power.

Yes indeed—and better than this, the **Elmore** jumped right from this first fifty-mile race into another five-mile race with a 50-60 H. P. car and won the second, hands down.

Yes indeed—and better than **ALL** this too—the victorious **Elmore** was just a demonstrating car which had just passed through one of the most trying trips imaginable over the worst roads and fords of California. All this, mind you, without a stop for overhauling or a halt for breath.

It's the evenness of the performance, of course, that's remarkable—and directly due, of course, to the valveless two-cycle construction and its resultant continuous flow of power.

Our interesting literature, called "Our Daily Mail," will furnish you with further facts.

Will you write for it.

PROPOSED GASOLINE-ELECTRIC POWER PLANT.

Baltimore, Md., June 7, 1907.

I have under consideration the design and construction of an internal combustion motor to drive an electric generator, the combination constituting the power plant for the operation of an electric truck of large capacity. (What the British trade calls the "Petrol Electric System.")

The motor should develop 40 H. P. The generator will be wound for 125 volts. To secure the minimum weight in the generator the speed of the motor should be as high as possible. The motor presumably will have three or four cylinders. A speed of 3000 R. P. M., or more would be desirable. The control will be through a variation of speed and variation of the field strength of the generator. I presume that such speeds are rather freakish in engine design and I have no knowledge of the practical limits of decrease of stroke and increase of piston area that may be safely adopted.

Will you kindly inform me as to the following points:

1. What do you consider the maximum speed in r. p. m., that may be practicable, with due regard to depreciation and maintenance and vibration, and with reasonable regard to efficiency?
2. Assuming a maximum speed of 3600 r. p. m. what would probably be the lowest speed at which the motor would operate reliably at its pro rata load corresponding to that speed?
3. What bore and stroke would you suggest for a 40-H. P., 4-cycle motor (3 cylinders or 4 cylinders), at the maximum speed you consider practicable?
4. I would like very much to have your opinion of the design of a motor to the same specifications, substituting 2 cycles for four cycles?
5. Authors of articles on automobile engines frequently state as obvious the greater prospects of success with air-cooling as applied to the 2-cycle motor, as compared with the 4-cycle. Why is this so obvious? C. G. E.

The conservative engineer sticks closely to things that have been tried and proved good. Engines have been made that would run up to 300 revolutions per minute, but this is so far above standard practice that I cannot advise working for such speeds. 1000 feet piston speed per minute is considered fast enuf. Short strokes throw more strain on the bearings, and coupled with high shaft revolutions make much bearing friction. At high speeds the poppet valve is not satisfactory, and the rotary valve is regarded as an experiment, altho I believe from my experience with them that they are all right if carefully made. The Lamberts are using motors of 6-inch bore by 4-inch stroke, and I have not heard of any trouble from these proportions. Such motors can turn 1500 r. p. m. without exceeding accepted safe piston speeds. You can probably fit the pistons loosely and by proper lubrication get up to 2000 r. p. m., with fairly good efficiency. I cannot advise trying for higher speeds for your purpose with the usual types of gas engines.

If you wish to try for higher speeds I would advise a 2-cycle motor with a compression chamber or cylinder so arranged that the new charge when drawn in is completely expelled into an intermediate chamber, so the next new charge may be a full one. The usual forms of 2 and 4-cycle engines simply do not get full charges at high speeds, and so fail to develop power anywhere nearly proportionate to the speed. One form of 2-cycle uses a long cylinder with stuffing box at lower end, and a hollow double-headed piston. The new charge is drawn into the space between the piston and stuffing box, and then forced by the downward motion of the piston into the interior of the piston From here it escapes into the upper end of the cylinder as soon as the exhaust pressure is low enuf to permit the check valve to open. Three valves are used and if the one into the cylinder is mechanically operated a larger new charge can get in.

High speeds contribute to smooth running if the parts are properly balanced for the impulses cannot overcome the inertia of the vehicle body in the short time allowed.

If you adopt such a 2-cycle with 4-inch stroke and run it at 2000 r. p. m., you ought to get the h. p. indicated by the formula. Diam. squared times number of cylinders divided by two. I would use 3 cylinders parallel or 4 cylinders on a 2 throw shaft placed horizontally double opposed.

I do not think there is much differenece in the matter of cooling. Engines up to 4½-inch bore can be cooled by air, whether 2 or 4-cycle. The 2-cycle has no exhaust valve to give trouble and only retains the hot gases about 150 degrees out of a total of 360; while the 4-cycle retains some of the hot gases to the end of the exhaust stroke or a full half of the time.

Increasing the maximum speed will not effect the minimum speed, if your carburetor is of as wide range as it should be. A carburetor properly should be adjustable at each end of its limit and automatically vary between. Double jet carburetors are supposed to permit double adjustment, but they do not appeal to me as the true solution of the problem. C. E. D.

TIRES FOR 6-WHEEL CAR.

Exeter, Me., May 4, 1907.

I am sending you sketch of my new automobile gear, specially constructed for use of steel tires, although drawing enclosed shows rubber tires, using front and rear wheels for steering, center wheels for driving. Which is preferable in your estimation for this particular gear, rubber or steel tires. Steel tires ride easier on this vehicle than any rubber tired car of the four

wheel type, manufactured at the present time, as I can get over rough roads, crossings and water-bars at high speed without the throw or bound of the four-wheel car. H. H. LINN.

The kind of tire is a matter of choice for the purchaser. I believe there will be many solid rubber, or even steel, tired vehicles used in future and your six-wheeler is a move in the direction of easy riding without pneumatics. I have often wondered that six wheels have not been used before this because of their smoothing effect on the road. Six wheel trucks are used on Pullman cars and the difference is very noticeable compared with four wheel trucks. If this is true on steel tracks surely the gain will be many times greater on rough roads. The public prefer air tires, because they have been educated to them on the best goods. Give them other tires at a lower price if ordered. C. E. D.

A QUESTION OF FLYWHEEL WEIGHT.

New York, May 25, 1907.

I have a De Diòn engine, weight 100 pounds, cylinder 3 3-16-inch diameter and 3 3-16-inch stroke; the flywheel weighs 60 pounds. I expect to use a ¾-inch flat belt, and am going to put it in a two-cylinder Curtiss frame. Don't you think the flywheel is much too heavy? What would you advise as a suitable gear ratio and what H. P. would this engine develop?—GEORGE ZOGG.

How heavy the flywheel must be is a matter to be considered with relation to the speed of your engine and cycle. If you can keep the engine turning rapidly you will be able to get along with very little flywheel, probably 40 pounds; but if you wish to run the engine slowly, no weight can be spared. The makers of that engine cut the weight pretty low for a single cylinder when they made it, and it seems unlikely that you can do much better without sacrificing something. Because of the necessity for high engine speed I would gear low; at least one-third lower than with a 2-cylinder engine of same power. You should get over 3 H. P. Better take off 5 pounds weight at a time and try in actual use. Also try several sizes of driving pulleys, until you get results that please you. —C. E. D.

CORRECT DARRACQ POWER RATING.

New York, June 1, 1907.

We note your response to "Subscriber," your issue of May 1, in re, the horse power of the largest six cylinder car the Darracq Company make, and your further answer as to what horse power the six-cylinder engine of 112x120 m. m. will develop at 1200 R. P. M.

The six cylinder Darracq cars are made in two sizes. The 40-H. P. model having 100 m. m. bore and 120 m. m. stroke, and the 50-H. P. model having 112 m. m. bore and 120 m. m. stroke.

Both of these ratings are figured on the abnormally low French rating, and are so placed in order to avoid the onerous French taxation on the cylinder size and capacity, so that both of these models might be conservatively rated at least 10-H. P. higher under our American practice and rating.—DARRACQ MOTOR CAR COMPANY, Alex. Schwalbach.

I thank you for the correction and regret that my reply was erroneous. I relied for my information upon a French chauffeur who seemed well informed as to the various sizes and ratings of foreign cars. C. E. D.

READJUSTING WORN CAMS, ETC.

June 2, 1907.

I own a 16-20 Locomobile car, 1904 model, and am not satisfied with the way the engine operates, although it is comparatively an old model. I don't see why it can't be made to "purr" like the newer engines.

I am going to thoroughly overhaul all mechanical parts such as bearings, brasses, wrist pins, rings, etc. Then will come the tuning up. The engine has automatic inlet valves. Now, what I would like to know is this: How would I go to work to secure the perfect operation of all four cylinders? Is it first necessary to have equal compression in all four cylinders? Is it accurate enuf to set one exhaust valve to open at 25 degrees, and in this way secure the distance from the top of the piston to top of cylinder head, and using this measurement as a check on the other valve openings? Of course, the commutator must make contact on each quarter of its revolution to secure balanced explosion. But what I am after is the "purr," and if you can suggest any method to be followed you would greatly oblige. F. A. C.

There would seem to be no reason apparent from your letter why your motor may not run smoothly. Measure present opening point of all the exhausts. I think you will find it earlier than 25 degrees. Adopt the one you think right as a standard and adjust the others to it. This may not be an easy task, for you will probably find the cams, rollers, etc., worn. Larger rollers may serve instead of new cams and larger push rods may also help. See that the valve lifts are to the same height as well as in the same time. Also that the valve springs are equally strong. I prefer marking the valve movements on the fly-wheel where each can be seen and compared with the next. The timer contacts, vibrators, inlet and exhaust pipes as well as the compressions should be all alike. Regard nothing as too insignificant. "Details make perfection and perfection is no detail." C. E. D.

HARDENING STEEL.

St. Louis, Mo., June 2, 1907.

I have trouble in case hardening soft steel. As a subscriber of your Journal I would be pleased if you will give me a quick method on same. GEO. L. WACHTER.

Case hardening consists in so treating the soft steel that its surface is converted into a carbon steel which will harden. The method to be used depends on the steel, the size and number of pieces and the results wanted. If a slight hardening of the surface of a single piece or of a few pieces will suffice, use cyanide of potassium or ferro-cyanide of potassium, which is cheaper and just as good except that it does not leave the metal quite so clean. Heat the steel cherry red and wet it with the potassium, which melts and becomes a liquid at such temperatures. Heat and wet alternately two or more times and dip red hot into water. Cold water will harden more than warm water and brine or a solution of sulphuric acid still hard-

Hosted by Google

er. Move the steel about in the water, for if you hold it still the steam bubbles will form a coating over its surface and prevent the water cooling it quick enuf. Small articles can be boiled in the potassium in an iron ladle or even sheet iron pan, and when they have had time to be penetrated to a sufficient depth can be picked out and dropt in the water. The fumes of cyanide are poisonous so do not breathe them.

For larger articles or greater depth of hardening granulated bone is used and commonly in a special oven. The steel pieces are packed in the granulated bone in cast iron boxes and kept red hot for several hours, often over night. When in the opinion of the workman they are properly converted, they are hardened in brine, water, or oil as may be preferred. I see no reason why the potassium will not also harden deeply if the red hot steel is exposed to it long enuf. Most soft steels will harden slightly by heating and quickly cooling without any chemical. C. E. D.

GASOLINE TURBINE.

73 Forsyth St., Detroit, Mich.
June 1, 1907.

Being a constant reader of the Journal, I take advantage of your department by asking your advice in regards to a gasoline turbine composed of four chambers. Would it be practical to have 75 lbs. compression in the intake pipe, and would the area of intake pipe have to equal the area of chamber in piston? How many strokes would it require to attain said compression, with compressor having a 3-in. bore, 4-in. piston travel? W. A. BLACKBURN.

You do not give enuf detail concerning your device to enable me to understand what you wish to accomplish, so my advice will aid you little, if any. Read Cassier's Magazine, January, 1907, for description of a practical gas and steam turbine. The number of compressor strokes required depends on the container you wish to fill. A single stroke of a good pump will give a pressure of 75 lbs. as you may readily determine by attaching a gage to a pump. Five strokes will be required to fill a container as large as the pump. A piston compressor uses more power than a turbine fed by it will usually give, so most of these attempts have been failures. Read everything you can get on the subject before spending any money and you will thus learn what has been done and avoid mistakes. Detroit's public library is well stocked with books as I know by personal use; or call on Parker & Burton, patent attorneys, who have a complete classified list of all U. S. Patents, and for a small fee can show you all the turbine drawings. C. E. D.

CLEANING CYLINDER WITH KEROSENE.

Toledo, Ohio, May 17, 1907.

Every one of my friends who runs on automobile tells me that about once a week he puts from half a cup to a cup of kerosene in each of his cylinders and then runs the engine until it has burned out for the purpose of cleaning the cylinders, and yet I cannot find in any books any advice or recommendation to do this. Will you kindly advise me whether you consider it good or desirable practice?

F. M. BRIGHAM.

Kerosene cuts the lubricating oil and loosens much of the dirt and carbon on the cylinder walls. It is good practice to use it, and it is recommended by many foreign writers. Water fed into a hot engine also serves to clean out the carbon but it may interfere with the next start. C. E. D.

CAUSES OF DETERIORATION IN RUBBER.

"How long will rubber retain its life?" is a question recently asked me by a prominent automobilist. I cited a number of samples of rubber that were in apparently as good condition at the end of six or eight years as at the beginning, and then went to my tool chest (a valuable asset in other days, but now a catch-all), and fisht from among the sundry articles in it several pieces of rubber that have been in my possession for 17 years. They are as soft and flexible as if new and do not even show air cracks on the surface, as old rubber often does. I have also in service as erasing rubber parts of solid tires of small diameter such as were used before pneumatics came in. These tires were made about 1889 and are therefore 18 years old. I understand that rubber does not deteriorate with age necessarily, and that the deterioration, if any, is due to causes usually preventable, and that one of these causes is over vulcanization. The rubber manufacturer lives by his trade, and in order to save time in vulcanizing, he is tempted to compound with the rubber more sulphur than is needed to properly vulcanize the crude material. Thus, for example, where two or three per cent. of sulphur is sufficient, provided the vulcanizing heat is continued for half a day, he will mix with the rubber 10 or 15 per cent. of sulphur and expose the mixture to the vulcanizing heat for half an hour. In this time enuf of the surphur has united with the rubber to properly vulcanize it, rendering it tough, elastic and all that good rubber should be. Unfortunately the remainder of the sulphur is still in the rubber and the vulcanizing process slowly continues, faster in hot weather, but a continuous process in all weathers. The result is that sooner or later the rubber becomes hard, brittle and "rotten." I have had pure gum tubes for delicate work, presumably the best that could be made, get brittle as sticks of wood in three months; while the tires mentioned, and a number of others, have remained in my possession for years without any apparent deterioration. It would seem probable that if users will insist on quality the rubber makers will furnish it.

The fabric employed in connection with rubber is supposed to lose its life after a time. This is undoubtedly true, not because of association with the rubber, but rather because of the moisture which, getting into the fabric, cannot dry out; so the fabric quickly rots. Care should be taken to protect the fabric from moisture to the fullest extent. If tires are known to be wet inside they should be removed from the rim and allowed to dry, for there is but little rubber inside to protect the fabric from this moisture. Small holes or punctures reaching into the fabric from the outside should be closed by vulcanizing at the first opportunity and for this purpose small portable vulcanizers are undoubtedly valuable.—C. E. D.

2 Cycle Engines

SHORT OR LONG STROKE?

I have devoted quite a little time on the figuring and thought of the 2-cycle type of motor, but before I proceed with expensive patterns, would like an experienced one to encourage me. I would like to know why nearly all two-cycle engines are designed with the stroke short. Would it not be practical to make one with 3½-inch bore and 5¼-inch stroke? The ports to extend all around the cylinder intake 11-16 inches and exhaust 15-16 inches. This, I think, running at 1000 R. P. M., ought to develop 8-H. P.

I would like to know the height of intake deflector, and distance from cylinder wall. Would it not be a good idea to shoot the incoming charge up and against the cylinder wall? Would 8 or 9 pound crank box pressure be swift enough for this speed? In designing the passage from crank box to cylinder, would you keep the cross section of port the same throughout the length? I have an idea that the velocity would be increased by making the port small at the crank box end, and tapering it slightly at the cylinder port end, but at the big end, have it slightly smaller than the cylinder port.

I will thank you in advance for this information, which will greatly help me.

ROBERT H. PYLE.

Probably, if you call on Mr. E. J. Gulick, Simplex Auto, Mishawaka, Ind., 5 cents per

Hosted by Google

trolley from you, and see what Mr. Gulick is building you will be the gainer. I regard the Gulick 2-cycle motor as about the best that can be done with crank-box pressure. Study the large 2-cycle motors, double acting, which do not use crank-box pressure. Consider this plan. Set a supply cylinder parallel to your working cylinder, capacity or piston displacement of supply cylinder same as working cylinder, cubic contents from top of exhaust port to cylinder head. The supply piston can be very light and packed with one felt ring. Drive this supply cylinder trunk piston with an outside crank set so as to end the supply piston compression stroke when your intake port closes. Your working piston stroke and supply piston stroke will of course have 180 degrees of crank shaft time, and you can have your intake port open from 70 to 90 degrees of crank-shaft angular advance. This will give you considerable compression before your intake port opens, so you will have a good initial charge velocity, but will make your charge compression stroke end at atmospheric pressure, and will make your motor more than twice the power of a 4-cycle motor same bore and piston speed.

All gas engines are made short stroke to save space and cost. I have seen a 2x12 gas engine give an almost ideal card, but the car-driving motor cannot have much more than 5-inch stroke in the room there is for it. Besides room considerations, there is not so much to gain by charge expansion with the gas engine as with the steam engine, and the trunk piston works out badly for length with a long stroke. The deflector is better, in my opinion, when formed by cutting into the piston sides than when projecting above the piston head, as the inside of the piston is cool. If you scoop out the piston wall for deflecting surface you can have your piston head stand one inch above the bottom line of your intake port when the piston working stroke ends. Eight or nine pounds crank-box pressure is twice usual 2-cycle practice.

Study the Gulick practice, if you are bent on using crank box supply, or the Reliance Truck practice. The Reliance motor is giving excellent results.

See also the shape of the trunk-piston and deflecting surface in the Du Brie small marine motor.

I think you intend to ask. Would it not be good practice to shoot the charge up against the piston wall, instead of the "cylinder wall," as you write. It is best, in my opinion, to make the piston wall the deflector. The applied deflector on top of the piston gets hot and causes self-ignition.

HUGH DOLNAR.

EXTRAORDINARY POWER DEVELOPMENT QUESTIONED.

In the May issue of the "Trade Journal," I noticed an obituary notice of Mr. C. P. Malcolm and a statement that he had built a two-cycle engine which developed 10-H. P. for 24 hours, with a total cost of 18 cents. This test was spoken of as a miracle. It certainly is a miracle or mistake. Assuming that the cost, 9 cents per gallon, which is a very low price, and that the cost of the lubricating oil was not considered, and that the engine developed 240-H. P., hrs., or its equivalent in heating effect, 615,600 British thermal units it has consumed per H. P. hour only 1-20 pound of fuel.

Then if the fuel was gasoline, carrying say 22,000 B. T. U. per pound, which is certainly a liberal figure in the two gallons consumed, there would have been 264,000 B. T. U., and as the engine developed 615,600 B. T. U., it operated at an efficiency of 233 per cent. Evidently there is a mistake either in my assumption or the stated economy of the engine, or all generally accepted thermo-dynamic concepts are wrong.

In my own experience with much larger gasoline engines, the best economy I have ever observed has been ¾-pound fuel per H. P hour and that only under exceptional circumstances. It was evident from Mr. C. P. Malcolm's writings that he was far in advance of most two-cycle designers, and everyone who could appreciate his work must feel a sincere regret for his death and a hope that someone will be able to carry out his plans. No one before has described two-cycle phenomena as Mr. Malcolm and I suggest that the "Trade Journal" might well collect and publish his work on the subject. Trusting that you may be able to explain Mr. Malcolm's engine test in more detail, and thanking you for 2-cycle motor information which I have read with much pleasure and profit, I am

P. L. HOAG, New York City.

Replying to Mr. Hoag, I would say that my notice of C. P. Malcolm's 2-cycle motor distinctly states that the cost of fuel and lubricating oil was 18 cents.

Circumstances alter cases. The fuel used was not gasoline, and cost only a small fraction of 9 cents per gallon. The actual costs were, fuel 12 cents, lubricating oil 6 cents.

The conditions were, motor locked up in a room by itself, with no attendance, for the entire 24-hour run. The work done was supplying electric current to a bank of electric light bulbs.

Mr. Malcolm's death notice was written by me, and I have Mr. Malcolm's motors in my control. HUGH DOLNAR.

BACKFIRING WHEN LOAD IS OFF.

Being a subscriber to your paper I would like a little information in regard to a gasoline engine which I have built. It is a two-cycle 3-port 4-inch bore, 4-inch stroke exhaust port, measures 1-inch x 3-inch intake port; is ½x3 inches. It seems to run all right when the load is on, but if load is thrown off it fires back in crank case and then stops. Have filled the passage from crank case to inlet port with woven wire cloth, but this does not help it any. Am using a Lunkenheimer generator valve which I have also tried on the crank-case, with no better results. F. W. BEEKE.

There is nothing about your motor, so far as your description goes, to hinder it from running, and one sheet of wire gauze, properly placed in the side-pipe from the crank-box to the intake port, should prevent crank-box firing. You probably have applied your wire gauze in such a way as to leave an open fire passage between the cylinder and the crank-box. If you have a deflector separate from the piston and screwed on the piston perhaps the deflector gets hot and fires the charge. Have you a throttle in the side pipe to throttle the charge when running with no load? HUGH DOLNAR.

MALCOLM ENGINES.

Brooklyn, N. Y.

I notice with great interest your item regarding the death of Mr. Charles P. Malcolm, on page 84 of the "Trade Journal," and the appreciation there contained.

I had written Mr. Malcolm before the May number came, but of course may not expect an answer now.

Will you kindly let me know whether the engine of which you speak as invented by Mr. Malcolm—viz., two-cycle, 10 H. P., running 24 hours at a cost of 18 cents, is now on the market or can be procured?

I am about installing a new engine in my motor boat and if I could procure one of these I should like to do so.

Are there any made on his lines with two cylinders?—R. W. KENYON.

I do not think Mr. Malcolm's engines are on the market, a thing much to be regretted. I feel that he, like many advance agents in the mechanical line, was more devoted to perfecting than to producing. The 2-cycle problem has been a difficult one and I think it is not fully solved yet, but progress is being made and there will be described in these columns in the near future a motor giving an impulse every revolution, without several of the disadvantages of the common 2-cycle. Fixt size ports and variable speeds have not permitted decent economy in the past, but this may be provided for in future.—C. E. D.

Steam Vehicles

J. A. KINGMAN

ACETYLENE GENERATOR FOR BURNER.

Plattsburg, N. Y.

The following will interest H. S. F. (page 135, June issue.)

I was in Burlington, Vt., a few days ago, where I saw two Stanley steamers fired up without torch, the burner being heated by an acetylene jet permanently attached to the car. Mr. E. A. Brodie, 105 Church street, Burlington, Vt., can give name of parties from whom attachment can be bought. I did not myself ascertain where the contrivance is to be had, as I do not use this gas for lighting up lamps on my car. The whole trouble of heating torch is avoided, and it takes not more than ten seconds to heat burner ready to light pilot and main fire. I had seen the contrivance advertised before, but this is the first time I ever saw it in use. It appears to save much trouble in firing up, though one must be careful not to melt burner tips with intense heat of the acetylene gas.—A. N. HENSHAW.

DRIVE FOR STEAM RUNABOUT.

San Bernardino, Cal.

I would like to ask you through the "Cycle and Auto Trade Journal" your opinion of the inclosed sketch for a drive for a steam runabout. Engine to be of the "Mason" type and drive by roller chain to sprocket on live rear axle. Engine to be placed only 12 inches from rear axle, so that all moving parts, engine, chain, sprocket and differential can be inclosed in one metal case and be splash lubricated. Entire power plant—flash boiler and engine—to be hung on a triangular angle steel sub frame to give three-

Proposed Drive for Light Steam Cars.

point suspension; two corners of frame to be pivoted to rear axle spring boxes and the third point pivoted to cross member of body frame under dashboard. Will the engine shaft and rear axle be far enough apart to give an efficient drive with chains of this type? Would a short chain like this one stretch enough in use to require some means of adjustment of shaft distances?

In general, between what limits can a chain drive be economically employed? Would 10 inches be too close for the shaft with above drive, and will a 1-inch pitch roller chain work satisfactory if shafts are 48 inches apart? In considering the above questions, it is understood that an efficient transmission that will give little trouble is desired.—CHAS. BRADSHAW.

Generally speaking, the larger the sprockets and the shorter the chains in any system of chain drive, the better. A very long chain drive has been found in practice to be undesirable, and all chainmakers are opposed to the use of sprockets having less than a certain number of teeth. It would seem, therefore, that the number of teeth on the sprockets would be a more important matter for consideration than the distance between sprocket centers.

The 1 inch pitch chain seems a little coarse. Should think smaller pitch would be more desirable. Of course, some methods of adjusting the chains should be provided for, but if the case inclosing the mechanism is oil-tight so that the lubricant does not leak out and dust does not work in, the need for adjustment should be very slight and infrequent.—J. A. K.

TROUBLE WITH PILOT LIGHT.

Walton, N. Y., June 7, 1907.

The letter from Mr. C. S. Lawton, of Woonsocket, R. I. (20 Bill street), received, and would like very much to hear his experience, and any suggestion he might make. He says his burner is a two-part burner, and my burner is also a two-part burner. I have been driving along the street and all at once the pilot light would go out and when the steam drops 5 or 10 pounds then the main burner vaporizes the oil but there would be no pilot light to ignite the gas—then, oh, what a smoke! I would stop and shut off the kerosene and wait a little and then light the pilot by using wood alcohol, but first would have to push the pin in the pilot vaporizer to clean out the carbon, then it would sometimes run an hour or two and sometimes not more than from 10 to 20 minutes. Now as to the burner, when it is working hard it will sometimes make a roaring noise that you can hear for half a mile (some call it whistling). Now if anyone can give me a remedy for these troubles I would be very much obliged to them.—E. P. RANDALL.

Would suggest that you clean the pilot light orifice regularly at some stated interval, not merely making an opening, but cleaning all metal parts thoroughly. The deposit of carbon is unavoidable, but if you will consider this carbonization as a perfectly natural process and look out for it regularly you ought not to ever have it bother you on the road.

As to the noise of the burner, alteration of the air adjustment ought to correct this.—J. A. K.

Natoma, Kansas, May 23, 1907.

I have a Locomobile steam runabout, and as rain water is scarce, I should like to know if I can use hard water successfully without ruining the boiler. How can I remove the scale from the boiler if it is already limed? Would it be more economical to move the regular gasolene burner and replace it with a kerosene burner, if gasolene is 17 cts. and kerosene 8 cts. per gallon? Will I be able to keep steam on as low pressure of air as with gasolene? I use more fuel than I think I should—how far should I get on a tank of five gallons on ordinary roads? What is likely to be the cause of my using so much oil? I keep my engine hooked up so as not to use much steam. Can I fit the regular "Loco" burner to burn kerosene? R. A. M.

Use rain water whenever you can and when you are compelled to use hard water blow off the boiler after the car has been used. Fire tube automobile boilers have never given very much trouble from scale, owing to the fact that the motion of the body on the springs gives a continual vertical washing of the tubes and about the only deposit which has ever been noticed has been on the lower ground sheet and this in the form of mud rather than scale, and which can be avoided by regular blowing off of the boiler. Dirty water is about as bad as hard water.

Certainly it would be more economical to use a kerosene burner than a gasolene burner so far as consumption goes, and if you make a change you will find it necessary to remove your present burner and install a complete kerosene outfit. This, of course, would involve considerable expense. It might be some little time before you had run the car far enough on kerosene to have saved enough to have paid for the cost of making a change. Trust the foregoing is clear. It might be well worth your while to make the change not on the grounds of saving a few cents every day in the cost of fuel, but on the grounds of convenience, as it is sometimes very difficult to obtain good gasolene when kerosene of uniform quality is everywhere available.

You ought to be able to run the car 8 to 10 miles on a gallon of gasolene—40 to 50 on one filling. J. A. K.

umn. The steering spindles and yokes are drop forgings forming jaw, or what is known as Elliot type steering knuckles. To obtain greater ease of steering the length of the knuckle spindles has been increased. Imported ball thrust bearings are used in the knuckles, and all steering connections have provision for lubrication.

FRAME.

The running gear frame is of channel section prest steel, arched above the rear axle to provide increased spring action without raising the body. The top and bottom flanges of the side bars extend inwardly at certain points to form integral gussets for the reception of the four respective cross members. The frame is cold-riveted thruout. There is no sub-frame. The frame is suspended upon four unusually wide, semi-elliptical springs. The rear ones are 56 inches long and the front ones 40 inches long. The front axle is of steel tubing of large diameter and heavy gage. The stationary sleeves of the rear axle are steel tubes prest into and riveted within flanged collars that are bolted to the differential and driving gear housing.

The wheel base is 123½ inches and the tread is 56½ inches. The wheels have been increased in diameter to 36 inches. They are of wood, of the artillery pattern. The front wheels have each ten spokes and the rear wheels twelve spokes. All wheels run on imported annular ball bearings of increased size. The front tires are 36 by 4 inches and the rear tires 36 by 4½ inches.

BODY.

The touring body, in its new combination with 36-inch wheels, has a longer and more stable appearance and obtains individually by arched recesses in the rear seat panels to provide clearance for the rear wheels. The body is made of aluminum over wood framework. The seats are upholstered in black straight-grain leather, over curled hair and with spiral spring backing thruout. To provide greater comfort, the rear seat cushions have been increased in thickness, lowered and are differently sloped. The standard finish is Richelieu blue and cream yellow. The price, with standard finish and equipment, is $4200, f. o. b. factory.

As a limousine or landaulet, the chassis is identical with that of the touring car. In the case of the runabout, however, there are several differences in keeping with requirements. The wheel base is 108 instead of 123½ inches. The motor and driver's seat are placed farther back on the frame than in the touring car, thus making the bonnet longer and properly distributing the weight. The divided front seat is lower, relative to the floor. The gasoline tank holds 27 instead of 21 gallons and is placed at the rear of the frame. The gasoline feed to the carburetor is by simple, automatic pressure system. Above the gasoline tank is a rumble seat. The standard tire equipment is 36 by 3½ inches in front and 36 by 4 inches in the rear. There are no other notable differences between the runabout and the touring car.

The "U. S." Model A, Gasoline Runabout

U. S. Motor Car Co., Upper Sandusky, Ohio, have just placed on the market a runabout propelled by a 12-H. P. gasoline, air-cooled, 3¼x3, 4-cylinder motor and are cataloging their first car as Model A. Ignition is by jump spark and a float feed carburetor is used. Oiling is by splash. The crank shaft is provided with 5 babbitted bearings. Speed changing is thru a sliding type speed change gear, which is ball bearing. Three forward and one reverse speed changes are provided. On the high speed the drive is direct with no gears in mesh. A double disk clutch of their own design is used which they claim starts the car smoothly without jerk and does not stick. Shaft drive is employed and a foot-operated service brake acts on the driving pinion shaft. Emergency brakes of the constricting band type operate on the rear hubs.

Four full elliptic springs support the body, each 40 inches long. The wheel base is 90 inches and the tread 56 inches. Wheels are 32 inches in diameter and the tires 3 inches cross section. A light, strong frame of selected hickory is used. Large wood fenders give ample protection from flying mud and do not rattle. The seats are of the individual type and are large and roomy and are fitted with soft edge cushions. A quick acting steering device is employed, operated by a hand wheel with throttle and spark levers on the steering post close to the driver's hand.

A roomy platform is provided in the rear of the body fitted with a double brass rail making it safe and convenient to carry parcels or a small trunk and thus adapting the car to light delivery service if desired.

The equipment consists of two oil side lamps, tool box on running board and full kit of tools. Price is $750.

It has been the aim of the makers to produce a light, easy riding car which would be economical of tire expense and they have also aimed to use the best possible material. Drop forgings are used wherever possible.

Charles E. Duryea, pioneer automobile builder, has become engineer of the Corbin Motor Vehicle Corporation, New Britain, Conn.

According to the reports issued by Colonel E. S. Fowler, appraiser of the port at New York, there was a falling off in the importation of foreign cars during the period from January 1 to May 1, as compared with the previous year. The total during the past four months was 384 automobiles, valued at $1,261,296.52, compared with 452 automobiles during the same period last year, with a valuation of $1,464,862.13. During the month of April 108 machines were brought in in comparison with 152 during 1906.

Let the man who is in doubt make a 50 or 500 mile test

in a Mitchell

Are you in doubt as to what car you want? Well, telephone any of our Mitchell agents and say, "Show me a Mitchell, and if I'm satisfied I'll buy." Then he'll come around with a 30-35 H. P. $2000 Mitchell and take you and the doubt for a spin of 150 miles—any time you say—and again next day—and again the next, so that you will cover some 500 miles and run up against every test an automobile will ever encounter. If you will do this, we can convince you that the *Mitchell* is the car you want.

We do not send a *salesman* with you—the car speaks for itself. All we ask is that you constantly remember the *price* of the Mitchell while you ride, and when you get back, that you talk to yourself *seriously* and say: "Can I, a business man, with business judgment, afford to pay from $1000 to $2000 more for any other car—could I get a better looking, a better furnished or more efficient car for the extra thousands? In fact, what *can* I get in any other car for the extra amount which *this* car hasn't 'shown me?'"

The Mitchell will answer those questions for you if you will let it, for it is the "show me" car.

If you will call up our agent and arrange a demonstration, the Mitchell will change your indecision into decision. It will convince you that it is the car you want by doing the things you want your car to do.

The Mitchell Motor Car Co., 30 Mitchell St., Racine, Wis., makers

ho has been prominent in the Boston
obile trade for the past six years.

. 1. The Bay State 40, wheel base, 122 ins.; gage, 56 ins.; tires, 34x4½ rear, 34x4 front; motor, vertical, 4-cycle, water-cooled cylinders, 4¾x5ins. and can give 40 H. P. on the road. The pro-ive sliding change gear gives three forward speeds and a reverse, with bevel gear drive to the ng divided rear axle. Tonneau body, side doors swinging to front, two folding seats to face all seven engers forward. Weight, 2900 lbs.; price, $3750.00, including mats, horn, tools and 5 lamps, all ready extended touring. Cape top is $175.00 extra.

s new car, the "Bay State 40," was
ned by Mr. George Temple, of Boston,
has had an extensive experience in prac-
motor car work, and has shown in this
car of his own production that he is
aware of the importance of supporting
chassis loads in the very best manner,
both strength and stability, and has
a full three-point support of the long

much greater distance had the weather per-
mitted. The car has always carried heavy
loads and been driven without mercy with
absolutely no repairs and only one substitu-
tion, that of a steel drop forged front axle
for the Parsons bronze casting first used.
Mr. Drisko is an expert driver, and the
control of the Bay State 40 was designed in
accordance with his suggestions, and as
might be expected, is very simple, conveni-
ent and wholly reliable.

It is not an extremely light car, its weight
being 2900 pounds empty, and about 3100
pounds with everything on. The first car
was geared 3½ to 1, and has more than
enough hill climbing capacity for Boston
service, hence the regular Bay State 40 gear
will be 3 to 1, giving plenty of speed and

¶ The light producing value of your lamp is not a mechanical question, but a scientific one.

¶ Our Mangin Lens Mirrors have been scientifically worked out to produce a certain result, and they do it, and the best result—the best light, is what you want on a dark night.

IT ALL depends upon the mirror—whether the light generated in your lamp serves to properly light the road, or is radiated in all directions and rendered ineffectual.

Bausch & Lomb Searchlight Mirrors

are constructed on scientific lines. They concentrate all the light rays into a solid beam, and just as a solid stream of water will carry a greater distance than a stream that is scattered, so will a solid stream of light. These mirrors will add about 50 per cent. light efficiency to your lamp and are made to withstand the heat.

¶ Insist on having a lamp fitted with the Bausch & Lomb Searchlight Mirror and *SEE* the difference. Every mirror is stamped B. & L. on its face.

¶ "PRISM" IS A LITTLE MAGAZINE we publish monthly. Not a mere advertisement, but a beautifully made and printed little publication about that world of wonder and beauty seen by the lens. Send us your name and we will enter your subscription FREE.

has been to find a speed and distance indicator that possessed *every* desirable feature at a price that *every* motorist could afford.

The Solution

is found in the

New Winchester

The new model (Model "H") possesses the same mechanism that gave its predecessor the reputation of being the one "dependable" indicator; the same patented application of the only correct principle of construction that makes the indicating hand absolutely steady under all conditions of the road and at any speed; the same strength of parts that makes it durable beyond the life of several automobiles, and the same workmanship that has made it known as "A Fine Instrument for a Fine Car." Add to this, that it has the High-Speed-Record-Hand which indicates the maximum speed attained. Now add the facts that shaft breakage is prevented by our new re-enforced case, and that we have perfected an attaching bracket that fits 90% of the cars.

The Sum Total of These Facts Equals Speedodometer Perfection.

The Packard Motor Car Co., Detroit Mich., finisht the last of its 1907 output on May 23, twenty-nine days of the schedule time for the completion of the 1129 cars ar ranged to be made for the present season and the testing crew, in celebration of th event, decorated the last car in the nationa colors, rigged two large American flags in front and paraded the car around the street of Detroit.

Thomas B. Jeffery & Co., Kenosha, Wis. have laid foundations for a new building covering about thirty-five thousand square feet and ten acres of land adjoining the north of the present factory has just been pur chased, on which new buildings will be pu up during the present summer. This ground extension makes a total area of forty-five acres owned by the Rambler people. The new buildings will all be of concrete con struction, both floors and walls, with stee saw-tooth roofs and skylights in the north exposures.

The erection of the Pennsylvania Auto Motor Company's factory at Bryn Mawr Pa., is progressing nicely. The plant will be so arranged that the raw stock will be taken in at one end from a railroad siding and the finished product coursing thru the building returning to the same siding. They will install a unique device for testing out the cars, to save them from the usual road

the Knox Motor Truck Company, Harry . Knox, president, Springfield, Mass., U. A., is now producing one per day of the tlas Runabouts, driven by a new 2-cylinder, cycle, water-cooled motor which is rated at H. P. This motor has important new atures for which applications for patents

JOURNAL. As will be seen, the present motor and car are very different.

PECULIARITIES OF THE MOTOR.

The Atlas Runabout Motor was desig by Mr. Dorville Libby, Jr., formerly of Francisco, Cal., now supervising engineer

Atlas 2-cycle Runabout, front. Front axle by the andard Roller Bearing Co., Philadelphia. Front heels on non-adjustable roller bearings, with ball rust bearings. Radiator, long, vertical tubes.

Atlas 2-cycle Runabout, rear view. Rear axle the Standard Roller Bearing Co., Philadelphia. B gear, hardened, 3½ to 1 reduction, spur balance g Rear wheels on tapered axle ends, key and nu tention. Axle bearings all hard rollers in hard and on hard sleeves, non-adjustable, ball thrust ings.

Wheel base, 90 ins.; gage, 56 ins.; tires, 30x3½ ins.; motor, 2, water-cooled, 4½x4 vertical cylinders, placed under the hood in front. Thermal circulation, no fan front, no wa pump and fan-armed fly-wheel. Planetary speed change, two forward speeds and a reverse, be gear to divided rear axles. Weight about 1500 lbs. Price $1400.00, including mat, horn, tools and t oil lamps. Folding top $75.00 extra. Cover for folded top $12.00 extra, making $87.00 for the compl folding top equipment. The top cover is not indispensable to the top, but is neat, cleanly and sa wear of the folded top.

ve been made, and was put into its present rm, as here described in detail since the ecember, 1906, New York Show. The At- s car shown in December last was driven

the Atlas Company. The first approxima to this motor design was made by Mr. Li in 1902, patent applied for. Broadly, Libby's improvement in 2-cycle gas eng

5. Atlas 2-cycle Runabout. Left hand side or in car, hood removed. See elevation of motor. picture well shows the simplicity of the 2-cycle These two cylinders, without valves, pump or ve same torque as a 4-cylinder, 4-cycle motor.

ly burned charge residue, and place the ge in the cylinder in a superior manner, y conducive to certain ignition of par-charges and complete combustion.

ese features give the Atlas 2-cycle mo-great probability of prompt starting, as as great flexibility of motor power. In of fact the Libby motors invariably, so

In 1904 Mr. Libby built cars driven by

Fig. 4. Atlas 2-cycle Runabout, right side o motor, hood removed. The shive on front of front board drives the mechanical oiler, 5 leads. The moto is water cooled, thermal circulation, tapering deliver pipe from tops of jackets to radiator. Fan fly-wheel no fan in front.

two 2-cycle cylinders, and in 1905 one of these cars came into the hands of Harry A. Knox of Springfield, well known as one of the early designers of American cars driven by air-cooled 4-cycle motors. Mr. Knox made many different designs of small gas-engines and was early impressed by the obvious generic advantages of the 2-stroke cycle, and

Fig. 6. Atlas 2-cycle Runabout-Chassis, right side, from front universal joint forward, showing nary brake 9¾ dia. x 2 ins., on line-shaft. This brake is pedal actuated and is fitted with an integral band, lined with Gandy belting and applied by a 3-hole lever. The chassis frame-sides are of ash

Digitized by Google

went so far as to build a 2-cycle motor in 1896, but was deterred by opinions of experts of that early motor-car day from proceeding with the 2-stroke cycle. When Mr. Knox began to run a car driven by a Libby 2-cycle motor he was impressed with its all-round superiority from first to last, and after driving this 2-cycle motor for more than a year he induced the designer to come to Springfield.

The cylinders have no valves, but there is one mechanically-operated crank-box valve, which, however, merely goes round and round with the crank-shaft, opening the crank-box to the carburetor when either piston goes up, if turned the right way, so the motor cannot be started nor run the wrong way.

This motor handles the charge and exhaust on a concentric plan, so that the charge comes in from four sides of the cylinder and

Fig. 7. The Dorville Libby 2-cycle motor. The crank-case intake port is covered by a plain disk-valve having a port, which is driven even turns with the crank-shaft, and prest against the carburetor delivery port face by light coiled-springs. This disk-valve has one port thru it, so located as to take mixture into the crank-case only when the motor runs in one direction. This intake-valve replaces the automatic valve between the carburetor and crank-box.

NOTABLE FEATURES.

This smart little Atlas roadster is a car for every-day service, moderate size, with power enough to be mighty busy week-days, good looking enough to go on the road Sundays and easy riding enough for moonlight wanderings.

Its wheels are on roller bearings, springs better than half-elliptics, a wooden chassis-frame and a 2-cylinder, 2-cycle motor that starts when the crank is pulled, and is flexible enough and strong enough to give from three and a half or four miles, a smart walking pace only, to 35 miles or more on high gear, which is 3½ to 1, making frequent speed-changes needless.

shoots up the middle of the cylinder and down next to the cylinder walls, giving an ideal charge entrance and charge placing in the cylinder for ignition. The exhaust goes out of the cylinder in four directions and is collected in an annular exhaust passage, opening to the muffler.

The chassis frame is of ash, light, stiff, strong, elastic with no sub-frame, and the motor and planetary, 2 forward speeds and a reverse change-gear are hung on 6 pieces of plain, straight angle-steel, two pieces bolted to the insides of the chassis frame-sides and four other straight pieces, two bolted to the motor and two to the transmission, go cross-wise of the chassis frame with

Hosted by Google

their ends resting on the angle-steel pieces bolted to the insides of the frame-sides on the slant, so that the line-shaft and propeller-shaft are straight with each other at normal spring-deflection.

The Atlas springs are all ¾ elliptics. Front springs 43x1¾ inches, 5 leaves in bottom and four leaves in top half member, jointed in

Fig. 8. Libby 2-cycle motor, front end of crank-box connection, showing the crank-box intake port. The cylinders are off-set ¾ of an inch. See Fig. 7 and caption.

front, tongued and grooved, perched 20½ inches front eye to middle of axle. The rear springs are 43x1¾ inches, 4 leaves in top half and 5 leaves in bottom member, tongued and grooved and perched 22½ inches from the front eye under the axle.

The Kingston carburetor is used, and the motor starts promptly and is always ready to work at any speed. A rectangular, galvan-

Fig. 9. Section of cylinder in B B, Fig. 7, showing exhaust ports, bridges between the exhaust ports, and the annular exhaust passage to the muffler.

ized-iron fuel-tank is placed under the driver's seat. The control is simple, and access to the driver's seat is made easy by jointing the one and only hand-lever, which is worked to give high and low speeds, so that it can be moved out of the way when the driver wants to enter the car.

BODY AND MUD GUARDS.

The car-body is of sheet aluminum, and the mud guards are carried down inside in front, and are continuous with the side footboards, so that the car is well protected. The inside mud-guards are rather short in front, but nearly all the 1907 cars are that way, and

Fig. 10. Libby 2-cycle Motor, piston construction. The intake is thru four ports open to the crank case at low point of stroke. These ports open freely to the central intake nozzle, directed straight upward. The charge rushes up to the cylinder head in a central column, and then spreads out to fill the cylinder much as may be, with the certainty of clean mixture on top when the charge is comprest. The exhaust is all round the cylinder, so the whole of the exhaust and intake volume movements are concentric and symmetrical. This engine is prompt starting, probably because of these new features of concentric intake and exhaust.

one might as well be dead as be out of fashion. With all seriousness, all the 1907 inside mud-guards seen by the writer are a little too short in front, and the right kind of a puddle goes to the front-seat passengers' faces with certainty and dispatch, tho not exactly with neatness, same as of yore, before the inside mud-guards were placed at all.

Hosted by Google

ON THE ROAD.

Wednesday, May 15, was a bright, clear ay, for a wonder, not so very cold, and an tlas runabout, fuel-tank full, with Frank I. Fowler driving and the writer as passen-er, hustled out of Springfield soon after

Fig. 11. The Atlas 2-cycle Runabout Control. The park and throttle are controlled by ratchet-retained evers on top of the hand-wheel. The steering is a orm and sector, hardened, worm end-shake adjust-ent, by Warner, Muncie. The high and low gears re had by the single hand lever, which is pusht orward for high gear and pulled back for low gear, nd is hinged to swing outward to give access to the river's seat. The ignition is dry cells to one coil a box inside the front board, with high tension istributor and jump spark plugs. The Lavigne me-hanical oiler, 5 leads, is on the inside of the front oard, and is round-belt driven. The left hand pedal pplies the rear-hub, internal, emergency brakes. The iddle pedal gives the reverse. The right hand pedal pplies the ordinary brake band on the line-shaft rake-drum. No muffler cut-out is fitted.

reakfast for a run to West Warren and re-urn, this route being selected because it as a lot of good macadam surface, plenty of ills and some of the worse surface of any ain road in New England, rough, sandy, rooked, stony and abominable in every par-icular. One notable point, known rightly as Mud Hill," has two living springs in the oadways, which keep it wet the year round nd give this hill the unique distinction of eing a steeply inclined and deeply rutted lay, sand and stone mud surface, absolutely actively improved, steam-rollers and s crushers and gangs of road-makers at w so that we had all sorts of hindrances sides the bad old-road surface. Time taken at known points, but no attemp speed was made, about 25 miles being maximum estimate of high rate. The had no speedometer, but had a mile reco so that total travel for the trip was kn Except up and down Mud Hill, and in place where roadmakers disputed our of way with a four-horse team and a p the car made the entire run on high gear, was all alive, courageous and able ev where, up hill and down hill, in deep and picking its way thru ruts and holes, over bumps and around big st with plenty of power, and unexpectedly e riding. The springs seem a bit stiff on sm road, but were just right for rough w and the wheel base is long enough to steadiness, and yet short enough to make machine handy in difficult places. Our mishap was the loss of a lamp, that on driver's side. The lamp brackets were too light discarded pattern in brass, and broke and the lamp got away without tice. The lamp brackets were change present regulars when the car reached factory at 11.50 A. M., having made miles round-trip, and taking four gallon gasoline to fill the tank full again, al exactly 14 miles to the gallon of fuel sumed.

There was no course open for speed, a short run was made later in the da which the Atlas showed 36 or 37 miles ily, and this runabout can probably mak miles on a good road surface. It is n noiseless and has almost no vibration.

The performance of the motor was fect, prompt start and plenty of power o high-gear for all sand and mud, and fo hills except the never-to-be-forgotten Hill, where the deep ruts and high b made a low-gear crawl the only pace p ble for any car.

England Leads in Isle of Man Races

The third annual contest for the interna-ional tourist trophy race on the Isle of Man, May 30, was won by E. Courtis, in a o-horse power Rover. The first contest or the international heavy car trophy was von by G. P. Mills, driving a 30-horse pow-r Beeston Humber.

A. A. A. Good Roads Board

mittee will be to secure federal aid to the improvement of at least the trunk r in the various States.

od and metal parts go, every part of the side surface must be worked over with hand-hammer, the file and abrasive paper il the curves are perfect from all points observation, and the templets show no iation from standard shapes and the sur- e is everywhere perfectly smooth and pared to take paint. The body is now dy for the upholsterers, whose work de- nds the best of materials and the most hly skilled handicraft, as well as large and borate special machines. The completely embled and upholstered body then goes the painters, who give it the final finish colors and varnish, again demanding both terials and skill of the highest quality.

This mere sketch of the operations of sheet tal car body manufacture, in connection h the illustrations made from photographs en expressly for this story, will give the der a faint idea of what it takes to pro- e that composite assemblage of metals, ods and animal products which very few

perfection, but the Smith Brothers, both y young men, say that there is as much roo to-day for body making improvement there ever was, and are busy now with n designs and details as they have been, co stantly, ever since they made their first lit car body in a tin shop, and undoubtedly w be until they turn their metal body busin over to their successors.

What the proportions of the Springfi Metal Body Factory will be when these t Smith Brothers who founded it are ready abdicate, is something not easy to foreca From $56,000.00 in 1903, to a round milli value of product in 1907, is a rapid grov for a new industry, but as yet there are o a few motor cars and a great many hor drawn vehicles in evidence. What will motor car body business be when the ho as a tractive agent is looked upon as most obvious reminder of former barb ism in modern civilization?

The "Cosmopolitan" Model C.

D. W. Haydock Automobile Manufactur- Co., 1930 Chestnut street, St. Louis, Mo., ve brought out a new model of their osmopolitan," called Model C, and here ustrated for the first time.

Cosmopolitan Model C is a motor buggy the reachless Concord type, possessing eat strength and flexibility. It has Com- or White Chapel body, 64 inches long, 30 hes wide; 5 leaf Concord springs, 2 in- es wide, 64 inches long; 1¼ inch axles, uare bed; Sarven wheels, 40 inches high, spoke, 1⅛ tread. Wheel base is 62 in-

controlled on the spark and throttle.

A friction disk transmission is emplo in which the fly wheel is the driver measures 19 inches in diameter, while driven disk measures 18 inches and is fa with tarred fiber. The differential is of spur gear type and placed on a count shaft that carries the small driving spro ets, not on the shaft carrying the shift friction disk. The transmission device the tanks are all under the seat and radiator is under the footboard. The cle ance under the axles is 20 inches, mak the car especially suitable for rough roa The maximum speed is 25 miles per ho

The "Cosmopolitan" Model C.

es; track 56 inches. Double chain drive employed and the rear sprockets are fas- ed to the spokes of the wheels. The en- e is a single 4½x4 cylinder, operating on two-cycle principle, placed vertically in

Brake is applied by pedal to the differen drum. The method of clipping the lon tudinal side springs causes the front a to act as an equalizer.

FOR A LONG TOUR

in foreign lands—along the Riviera or the Valley of the Rhine or through the far West—your car must be one you can trust. Examination is not surety enough—you can't see the quality of steel. Practical tests are not severe enough. The only test you can rely on is the reputation of the **makers** and the **car.** Here are two significant facts:

The Makers of the Haynes Automobile built the first American gasolene car, erected the first American automobile factory, and have been making Haynes cars for **thirteen years.**

A regular **stock model** won its place on the American team in the Vanderbilt Cup Race against special cars of double its power, and in the Cup Race itself, its perfect regularity and wonderful endurance were the feature of the day. No harder test of a car has been given. It proved beyond question the Haynes quality and reliability. For long or short tours, abroad or at home, the Haynes is the car you can trust.

Remember, when you buy a Haynes you buy America's best.

EVERY STUDEBAKER CAR IS CAREFULLY TESTED BY ROAD EXPERTS, AND MUST PROVE ITS EFFICIENCY UNDER HARDER USAGE THAN THE AVERAGE CAR IS EVER CALLED UPON TO ENDURE

The road tests through which every

Studebaker

car is put, before it is ready for shipment, are indisputable evidence of the thorough manner in which Studebaker automobiles are constructed, and explain why they give such uniformly satisfactory service when touring over rough and difficult roads.

Studebaker automobiles are not tested on a smooth race track, but on a seven-mile course over rough and hilly roads. As shown in the illustration, a seat is attached to the chassis, the rear of which is weighted down with sand bags weighing 1,000 pounds, to give a maximum load. The car is then taken out upon the course and every detail of its construction is thoroughly tested.

After a Studebaker car has been passed by our road experts the only thing remaining for the purchaser to consider is the style of the car desired and the price

Rushmores Abroad

The phenomenal popularity of the Rushmore Searchlight at home is not more remarkable than its rapid rise in favor abroad. A year ago we thought our exports worth talking about (and they were), but they have increased four-fold since then. In England Rushmores are the standard equipment on Mercedes and Fiat cars, and are furnished as an option on most of the high class cars. In France their sale has advanced by leaps and bounds, and cheap "imitation Rushmores" are becoming as common as nearer home. In Berlin and Milan new branches have lately opened with large orders already placed. In every European country and in the British Colonies leading personages among royalty and the nobility can be counted among Rushmore owners. Every motorist who tries a Rushmore admits its tremendous superiority over every European type of lamp, and to own one is even more a mark of sporting distinction than here. When a record run is to be made, Rushmores are more and more frequently selected, no matter what the stock equipment may be. The 45 h. p. Mercedes with which the London-Monte Carlo record was lately cut to 29 hours 20 minutes carried Rushmore Headlights and Searchlight, and much of its success was credited to the high speed thereby made possible through a stormy night. The Gobron Brillié cars in the London-Paris **"Entente Cordiale"** motor service are similarly equipped.

And RUSHMORES are the only American gas lamps sold in Europe. Is not this fact suggestive?

Thomas Flyer

Hundreds of cars in daily use for months. Some have traversed thousands of miles over roughest kind of roads. One made over 8000 miles. Another 10,000 miles. **Not one complaint** of tire trouble.

REASON found in splendid policy of providing 1500 pounds surplus tire capacity by equipping cars with larger tires and wheels at additional cost to us of over $100. Front tires 36 x 4 inches. Rear tires 36 x 5 inches.

PROVES again that we will not only eliminate all structural troubles but eliminate practically all operating troubles such as tire troubles by use of big tough tires and ignition troubles by the use of a double ignition system.

All this is submitted for the cool and critical buyer—the conservative business man. Regardless of price no other large car can present such a grand record.

'he propeller shaft has universal joints each end, not the same, no construction ails given.

'he gear box is a steel casting with an minum plate applied to the right-hand side. e change gears, 3 forward speeds and a erse, are steel and hardened. The en- ement is progressive, and the control tage permits attempted gear shifting with clutch engaged.

BRAKES.

'here are internal shoes in the rear-hub ms and in a line shaft drum at the rear of the gear box. No exterior brake ds. The internal brake shoes are all

hand and left-hand screw is engaged by ha nuts on each side, one right- hand, the oth left-hand, these half nuts being prolong downward to push against the bell-cra arms of the globe ended steering arm.

The steering-wheel moves only thre quarters of one turn to give the full swe of the front wheels. This is common Fren touring car practice. The French race have, commonly, one full turn of the stee ing wheel for full sweep of front whee and 1907 American touring practice giv 1½ hand wheel turns for full sweep of fro wheels.

The outside hand lever is latched, a when pulled backward first disengages t clutch and then applies the emergency rea hub brakes.

t he goes, and it is sometimes money in pocket to know how fast he was going the time of some particular happening and able to swear to his actual miles per hour ore a magistrate, as in case of arrest by peed-curbing minion of the law.

Because of this contingency and several er considerations, many devices intended show the pace in miles per hour of motor s on the road have been put forward. h devices, variously known as "Speedom-rs," "Speed Indicators," "Autometers" and

form, a ball or weight of metal at the f end of a hinged lever, which is often doubl for balance, giving the governor as co monly seen two balls, one on each of t levers, hinged at the top, so that the balls a arms drop down to low point, with the leve depressed as far as the mechanism will perm when the governor stands still. The notal peculiarity of this mechanical combinati is the fact that the balls will separate, sprea ing the lower ends of the arms apart a c tain fixt distance, when the governor is

Fig. 1. Principal machine shop floor, Springfield Motometer Factory. The tools are by the best Am can makers, which are the best in the world.

on, have depended on some application of well-known "butterfly" governor, prob-y first used to regulate the motion of wa-wheels, and applied about a hundred years by James Watt to regulate the movement the steam-engine. The "Motometer," made sold by the R. H. Smith Mfg. Co., ingfield, Mass., U. S. A., comes into this terfly-governor class. The R. H. Smith g. Co. began business in 1865, as makers small manufactures in metal, requiring st accurate construction, was very suc-sful and was incorporated in 1883, and be work on the Motometer in 1902.

n the Motometer the scale is of brass, sil-plated, with the figures dead black. The veling index is black, stands still at the rect scale graduation, is easily read by the ver, and is covered with glass. The body

volved on its axis, and this spread or rise the governor balls varies with the variatio of the governor speed, while at the same ti the balls will stand at exactly the sa height and same distance apart so long the revolutions remain constant. The ba weigh each about three-quarters of an oun The coiled spring on the governor shaft sists the rise of the balls, hence the lifti power of the balls at any point of rise m be the same as the downward thrust of t spring, and the spring resists any upwa movement of the balls by jolting of the c while centrifugal action of the balls resi any drop of the index by jolting. The spri tension is 2⅛ pounds at 15 miles, 3 3- pounds at 30 miles and 4 6-16 pounds at miles. The total weight of the revolvi

Because the governors must be exactly
ke it is of the highest manufacturing im-
rtance that any speed measuring instru-
nt should have the fewest possible num-
of pieces, and for this reason solely the
trument here described takes the smallest
ssible number of differing parts, and lifts
l drops the index to make it travel up and
wn the scale directly from and by the rise
l fall of the governor balls, with no inter-
sed lever or other mechanism whatever.

The parts are made duplicates in size and
m, and the only thing about them which
fers is the long coiled spring which resists
lift of the governor balls. These springs
skilfully made and afterwards subjected
a course of treatment tending to produce
iformity of action, but they still have very
ght tension differences, which are correct-
by adjusting the top spring-abutment.

It will be seen that the accuracy of the
ding depends wholly upon accuracy of
rkmanship and wear can do no more than
ke the index stand a very little too low on
scale, and so make the reading an almost
perceptible trifle below the speed. In
nt of fact, the loads on this little gover-
r are so very small and are borne on
er washers so nearly indestructible under
ht loads that no wear was shown by a
otometer after 14,000 miles run on a car,
maximum mileage yet made by any of
se instruments submitted to inspection of
makers.

The instruments are so nearly alike that
o of the three shown on the "exhibit
nd" were taken off, and the writer was
mitted to select others from stock, which,
en placed on the stand, gave the same
dings as those which they replaced. This
periment was more than once repeated,
th random selections by the writer, and
readings were practically identical.

DRIVING.

The common method is to drive the speed
asuring instrument of whatever form, from
front wheel of the car, thru a flexible
aft. In the case of the Motometer, this
xible shaft is made of overlying coils of
no wire, alternately right and left hand,
encased in a flexible brass-wire tube. Most
the failures come from giving this flexible
aft bends of too small radius. If properly
ced the flexible shaft described has a long
e, so long as to be yet of unknown dura-
n, as the instruments have been made to
vister 20,000 miles with six-inch shaft-
rve radii, and the shaft was yet in good
ndition. In this connection it may be not-
that direct connections can be made from
e car line-shaft with rigid shafting and
ar wheels to the Motometer mounted on

stores shows beyond question that th
speed indicators are well enough built to b
credit to the classic locality of their nat
ity.

"But," says the ordinary observer, "here
this index held up only by these little
volving balls—surely the least jar or bou
of the car will make the index dance up a

Let a Hotchkin Take the Jolt

A piston working in a circular cylinder alternately forcing glycerin through a large check valve and a small needle valve, is the principle of operation.

On the downward or compressive motion the glycerin passes through the check valve without resistance, and returns to the cylinder, allowing free play to the springs.

The slighest pressure on the recoil closes the check valve, the piston reverses, and forces the glycerin through the needle valve, which is **regulated from the outside** to the exact pressure required to check the recoil and bring the car back to its normal position, slowly, without jar or jolt. Once regulated, they require no further attention.

THE HOTCHKIN Anti-Jolt Device will check the recoil of the heaviest spring, going at full speed, over the roughest road, so you'll never know but what it was an asphalt pavement. It makes possible greater speed. You can go 40 miles as easily, smoothly and comfortably as you now go 15; give better traction and lengthen the life of your tires by eliminating all the jolt and throw from the up-thrust of the springs. It does not interfere with the downward motion of the lightest spring, but

It Positively Checks the Recoil

of the heaviest springs, bringing the car back to its normal level easily and smoothly. Write us for further particulars and how to get a set on 30 days' trial—at our risk.

ectly indicating the actual velocities of correct fluctuations in the pace readings.

New Rambler Models

wo new Rambler models have just been ıght out by Thomas B. Jeffery & Co., osha, Wis. They are equipt with the e type rear axle and transmitting mech- m which have met with such success on del 24. The new models are known re- tively as Models 147 and 245.

Iodel 147 is designed to meet the demand a reliable four-cylinder touring car with fortable seating capacity for five and suf- nt power to permit travel on ordinary ntry roads.

he motor is a 4-cylinder 4½ in. bore and ke, and develops 20 to 25 H. P. The nders are cast separate. The crank case f special aluminum alloy. The rear axle dentical to that used on Model 24. The e housing is heavy seamless steel tub- made integral by a special process, with aluminum differential housing.

he frame is of prest steel with strongly ced cross girders securely riveted in place. e rear springs are full-elliptic and the nt semi-elliptic. The differential is of the r gear type.

The clutch is of the cone type, leathe faced with a ball bearing to take the sprin thrust. All tendency of the clutch to bin or to get out of line is removed by a doub universal joint located between the clutch an the transmission. The transmission gear of the new Rambler progressive sliding gea type, located on the forward end of the pro peller shaft, thus dispensing with the usu universal clutch between speed change gea and propeller shaft.

Control is by tilting wheel beneath th steering wheel, which regulates the thro tle, and a ratchet lever for the spark. Tw brakes are provided, one, consisting of e panding rings, acting on the inside of th rear wheel hub drums, is operated by pedal; the other, constrictive bands acti upon the exterior diameter of the hub drum is operated by a lever.

The body is well and strongly made. Th frame work is seasoned ash braced wi angle steel. Seat backs are made of she steel. The finish is an attractive shade royal blue, striped with a fine gold line.

The price of the Rambler 147 is $1750, i

Rambler, Model 147, 4-cylinder, 4½-inch bore and stroke; 20 to 25 H. P.; prest steel frame; full-elliptic springs rear, semi-elliptic front; spur gear differential; new Rambler transmission. Price $1750, including cape top.

gnition is by jump spark, for which cur- t is furnished by a 6-volt 60-ampere rage battery used in conjunction with a ndard four-unit vibrator coil on the dash. e timer is of their own design and is so anged that the terminal posts for the es are stationary and the wires conse- ntly do not move as the spark is ad- ced or retarded, and the tendency of the es to loosen and break is accordingly nimized.

ubrication for the motor is provided by

cluding cape top with full equipment of si curtains and storm apron.

Model 245 is identical in every respe with their Model 24, described in our Marc 1907, issue, page 129, except speed chan gears, final drive and rear axle constructio

The rear axle is the floating type wi the road wheels running on roller bearing the inner members of which are seated the extreme end of the axle housing. T inner ends of the shafts are supported in t differential and carried on roller bearings

Be a practical motorist—learn about an automobile, at home.

You can do so easily, quickly, thoroughly, d completely by reading the series of eight lendid lectures now offered by The Corre- ondence School of Motor Car Practice of rrytown, New York.

These lectures—the first set of actually prac- al instructions for understanding and run- ng an automobile that has ever been prepared were gotten up by the Technical Department the Maxwell-Briscoe Motor Company (mak- s of The "Maxwell") under the personal pervision of H A. Grant, M E. They cover e history of m otor driven-vehicles exhaust- ely, define every part and principle of gaso- ne engines, give pointers on the care and eration of a car, etc., etc., never before put writing. A feature which makes them un- ually valuable is that they are illustrated with me *fifty original drawings* of motors, parts, etc. The actual money value of these lectures to yone interested in automobiles can scarcely be over-estimated. No automobile o driver or student of automobile affairs can to be without this remarkable work.

Whereas the ordinary course in a Corre ence School costs from $25.00 upwards, a quires many weeks for completion, this —the finest ever issued—may be obtain cluding a series of questions accompanyin lectures, and "The Making Of An Au bilist," by H. A. Grant, a fine book pages, illustrated and bound in moroc *complete, for only $5.00.*

Owners of "Maxwell" cars who will w us giving the number of their cars, an date of purchase, will be supplied with a plete outfit at $3.00, to cover cost of pri binding and mailing.

The edition of this material is limited early orders are necessary to insure getti complete series.

Save 27 Minutes

The usual time required to replace a punctured tire is 30 minutes. With the

CRESCENT Removable Rim

(Formerly Harburg)

a complete tire change is made in 3 minutes, by the watch.

The above sectional view shows the permanent beveled band, fitted to the wheel felloe, the adjustable rim holding any regular make of clincher tire, and the hinged clip, six of which are used to hold the rim in place.

Extra tires and rims are always carried—the tire being inflated at home before starting on a trip.

When a puncture is experienced, the damaged tire with its rim is removed and the extra rim and inflated tire is quickly bolted to the wheel, the entire operation consuming but three minutes.

Nothing could be more simple. Irritating delays are absolutely done away with. All parts are galvanized, nickeled or bronzed, thereby preventing any possibility of their rusting tight.

Spark and Throttle Control Head of Types C and E.

anchor and gas tube are of seamless cold drawn tubing; spark rod 5-16 inch Bessemer and the control head, which is stationary, is yellow brass highly polished and lacquered; the steering mast is covered with polished and lacquered seamless brass jacket. The gear is made in three types, viz C, D and E.

On types "C" and "E" the new controller head is fitted. The throttle control levers are lockt by friction, giving a very smooth action, and permitting of a very fine adjustment of gas and spark. Type E gear is for cars weighing from 2800 to 5000 lbs. and type C for cars weighing from 1300 to 2800 pounds. Type D is for gasoline cars weighing up to 1300 pounds or electric vehicles up to 2200 pounds. The control for this type is stationary, comprising a ratchet form of new design, operated by two vertical levers which are connected by piano wire with two bell cranks at bottom of gear. Prices are as follows: Type E, $62; Type C, $52; Type D, $35, including in each case control head, hand wheel, column and bevel gas and spark gears.

New Rushmore Lamp Factory

The automobile branch of the business of the Rushmore Dynamo Works, of Plainfield, N. J., has grow to such large proportions that they are erecting, at a cost of $100,000, a new factory to be devoted exclusively to this branch of the business, and will retain the old plant for locomotive and marine searchlight manufacturing. The new buildings will be of reinforced concrete construction, the main building to be 250 feet long by 50 feet wide and two stories high. The plans call for the erection of two wings, two stories high, each 200 feet long. A separate power house, 50x50 feet will also be erected and the equipment will include a 200 H. P. Koerting producer gas engine, which with dynamo will weigh 80,000 lbs. Another gas engine of 75 H. P. will be installed for emergency use. Most of the machinery will be driven by electric motors on the group system, but a few of the heavier tools will have individual motors. There will also be a complete brass foundry, one story high, and measuring 50x50 feet.

Sunberg Forgings

J. H. Sunberg Co., Kinzie and Carpenter streets, Chicago, Ill., make automobile forgings on order. They do considerable business in the forging of crank shafts and connecting rods to customers' drawings. Their principal

No Shoe—
No Hoof;
No Hoof—
No Foot;
No Foot—
No Horse!

You know that the fabric is the strength—the very life of a motor tire.

The protection of this fabric from cuts and exposure; from dampness and rot, is one of the chief functions of the *tread.*

A tread that peels at the edges or comes loose anywhere, admits water and dirt; causes blisters, rotting and the ultimate destruction of the tire. A tread that is not tough enough to resist the grinding road-wear soon exposes the thinner covering of the shoe to wear it cannot resist. "No tread—no shoe; no shoe—no tire!"

That's why a *tough* tread is important.

That's why a tread should not be cemented to the casing, but should *be an integral part of it.*

The Goodrich Tread is made of the toughest rubber known.

The Goodrich Tread is literally—*"The tread that won't come off!"*

And that's why

Two Hands are Better Than One

and the Jones Speedometer with one hand is the standard Speed Indicator of the world.

The "second" hand ind.cates the Maximum speed.
It remains permanent at the highest point until reset by a push on the stem
The hand drops automatically and instantly to the speed at which the car i
at that moment traveling.

The Jones Speedometer with Maximum Hand provides indisputable proo
against unwarranted arrest.

When reset at officers command to stop, its protective value is obvious.

The resetting stem may be sealed, immediately revealing any unauthorize
use of the car.

By a simple turn of the resetting stem the Maximum feature may be dis
posed with and both hands made to act as one, showing variable speed only

Complete description of this remarkable instrument will be found in "The Speedometer," a bulletin on speed subjects. Simply send a request to Dept. 12.

control which is said to be very effective upplying fuel in proportion to the de-d for it. This is accomplished by means single adjusting screw, and by means t, even the novice in the operation of or cars can adjust his carburetor so as give a uniform and invariable mixture out the entire range of operation of the or.

he Hagar Carburetor, aside from its float rol of gasoline supply, has no valves, no ngs, and no vibrating parts requiring ad-ment or subject to wear. It has no small ces to stop up with sediment, and is en-y accessible for examination without the ge of any adjustment.

e show herewith exterior and sectional s of the angle or side outlet type of this uretor. The gasoline enters thru the (G) with union attachment, and passes he float chamber thru the screen (H), re any sediment that might interfere with operation of the float valve is deposited. screen is readily removed for cleaning lisconnecting the union, and is of large city and not readily filled up. The float e (R) is controlled with a powerful lev-e by the float (F), the fulcrum of which

passing up and thru the throat (B) relatively high velocity, and in so doing pr ducing an inductive effect thru a numb of small openings (C), radiating from th gasoline nozzle (N). This inductive effe causes a partial vacuum in the chamber (I which draws up gasoline thru the nozz (N), and sprays it thru the openings (C where it is thoroly evaporated by the passin air current. The quantity of gasoline di charged can be regulated, by means of th regulating screw (J). When this screw tight down on its seat, the effect of the va uum formed in the chamber (J), is at max mum and a discharge of gasoline greate than required, can be obtained. If this scre be backed off from its seat, however, a passes in thru the opening so made in th top of the chamber (I), the vacuum is pa tially destroyed, and a less amount of gaso line drawn in. When once the regulatin screw (J), is properly set, the quantity o gasoline discharged remains practically pro portional to the rate of air flowing thru th throat (B), and results in an explosive mix ture of remarkable uniformity thruout th entire range of the operation of the motor.

The throttle valve (D), is of the rotatin type, consisting of a brass shell rotating wit the plug (L), by means of the operatin lever (K). This lever can be set to operat from any direction in a horizontal plane, an

The Auto Supply Co.
1733 TO 1737 BROADWAY, N.Y. NEAR 55TH ST.

Smooth-On Iron Cements

Smooth-On Cements are chemical iron compounds that withstand fire, water, gasoline, steam or oil. When hard they become a metallic iron that expands and contracts the same as iron. This makes them valuable for permanently repairing cracked water jackets, leaky radiators, leaky exhaust pipes or mufflers, around pipe connections, loose nuts, etc., and also for general steam and hydraulic work.

Every automobile owner should carry a Smooth-On Repair Package as breaks and accidents, which have heretofore been cause of long delays, are now repaired permanently in a few minutes.

Smooth-On Repair Package contains a one pound can No. 1 iron cement; a one pound can elastic cement, a roll of tape and the Smooth-On instruction book, which tells when, where and how to use the different Smooth-On Cements.

PRICE, $1.00

We have also numerous other articles of great interest to users of automobiles and shall be pleased to mail a COPY OF OUR NEW CATALOGUE (which just reached us from the printer) to anyone interested.

Our three distinct departments of

Supplies, Apparel, Tools and Hardware

comprise everything that is practical and useful to the motorist and repairman. We are marketing the product of reputable manufacturers only and absolutely guarantee everything exactly as represented. It will pay you to visit our establishment which is the largest of its kind in the United States.

amps from the seat. This device shows care and experience on the part of the inventor. It is not connected in any way with the ignition system of the car, the inventor feeling that it is best not to add to the complication of this function of the propulsion outfit. Being operated from a separate battery also makes it applicable to steam cars as well as gasoline cars.

The "Auto-Light"—small cut shows device fitted to lamp and the long narrow cut shows the method of breaking the wire connection, by means of the lock plug, when the lamp is removed from the car.

The "Auto-Light" outfit consists of the battery, a small dashboard coil with switch, three secondary wires, extension lock plugs, special burner and a primary wire. One of the secondary wires is run to each lamp and one to the car frame. The extension lock plugs are for the purpose of quickly disconnecting the wires to the burner when it is desired to remove the lamps from the car. It requires but a half hour to attach the device, the operation consisting of passing the wires thru the lamp back of the burner and screwing the burner into position. A spring near the burner permits adjustment of the device to any sized lamp. The whole outfit lists at $20.

The "Quick Sure" Terminal Holder

To meet the demand for a terminal holder for ignition wiring that could be used in securely and quickly attaching the wires or

compression spring and steel pin whi swedged to the base. To connect a wi terminal to this holder the knurled cyl is lifted against the pressure of the pression spring high enough to slip th minal under the projecting arm which thru the eye of the terminal and thr base of the holder. It is securely he

The "Quick-Sure" Terminal Holder in Unlock Lockt Positions.

this position by the strong compre spring within the knurled cylinder, locking the terminal in its position so no amount of pulling or shaking will lo it. The terminal can be unlockt by si lifting the knurled cylinder. The ter holder illustrated is known as style A can be used for any style of conne They also make a style B, especially ad for spark plugs. In this type the kn cylinder is directly over the center o spark plug, instead of to one side, style A.

The J. & G. Curtain Fastener

The J. & G. Curtain Fastener is man tured by Jonah & George, Merrimac, who claim that its construction makes possible for the curtain to become unfas by flapping or otherwise, and yet to be ple and easy to open or close. The fas is made in single, double and triple to fit all thicknesses of curtains.

"Invincible" Steel Tire Armor

accompanying cut shows a wheel fitted the Invincible Steel Tire Armor, the ct of the Invincible Tire Armor Co.,

flanges for traction and strengthening purposes. The plates are the only parts of the armor which touch the tire or wheel. The side of the armor consists of a link which fits into a slot in the main plate and covers side of the tire. This link slides in the slot, causing main plate to give with the pressure at ground. It is made from 14-gage steel. Attached to this link is a smaller link, which fits into a slot on the middle or sliding link, and connects the hole hinge to a ring.

This ring sets clear around the wheel beside the clincher, but does not touch it. The rings come in halves, bolted, so that the armor can be put on or taken off in halves, and quickly. This ring has slots for each set of hinged plates over tire to ring on other side of wheel. It is made from one-quarter inch steel. A full set of four armors weighs about 72 pounds. It requires a little more to start the car on account of increased traction at ground, but it is claimed that after car is started the increased weight of wheels and better traction causes car to run steady, and with less throttle than with naked tire.

The "Mianus" Gasoline Separator

The Mianus Motor Works, of Mianus, Conn., have designed a simple gasoline separator which is claimed to do the work very effectively. Referring to the sectional cut here shown, the brass screen or strainer is attached to a bushing that screws into the

"Mianus" Gasoline Separator.

top of the separator. The gasoline enters at "inlet." Water and dirt settle at the bottom of the bowl, while the gasoline flows upward thru the screen to "outlet" on its way to the carburetor. Water and dirt are easily removed thru the drain cock.

All the winning cars in the Targa Florio race were fitted with Bosch Magnetos, made in Germany. These magnetos are distributed to the American trade by Robert Bosch, New York, Inc., 1947 Broadway, N. Y. City.

wrenches, which are notable for their strength, lightness and durability. A number of sizes are offered and special sizes can be furnisht on order.

Sponges and Chamois Skins for Automobilists' Use

G. H. Worcester & Co., 35 Exchange street Boston, Mass., are selling Rock Island sponges and high-grade chamois skins for the automobilists' use. The sponges are claimed to be the best obtainable, coming from the rocky shore of Nassau. They vary in size from very large to as small as an orange; the large ones are the toughest because they are the oldest, and are universally used by the automobile people. Sponges are sold at auction by the natives to brokers who buy for the large houses in New York and London. These people maintain their own packing houses, where the goods are prepared for market. The process of packing and preparing consists of drying and curing the sponges, then packing them in bales when they are then ready for shipment north Their chamois skins are oil tanned.

"Healy" Inner Tube

The Healy Leather Tire Company, of 90 Gold street and 1906 Broadway, New York have been selling for some time an inner tube which they claim is giving universal satisfaction. This tube is made of a very high grade of red rubber, having a peculiar composition which gives it extreme toughness. They are wrapt in an unusual manner which gives a smooth finish and nice appearance. The joint is also made by a new method, which makes it so strong that it is absolutely impossible for it to separate. The company guarantees to repair all punctures

urnishing the trade with lamp num-
omplete ready to install, has lately
on the lamp door. The ends are longer than needed and the surplus is cut off to suit the particular lamp to be fitted.

The frame and figures are made of aluminum, and the spring is of phosphor bronze wire. The grooves which hold the figures

Fine's Removable Lamp Number.

at top and bottom are partly open before the figures are fitted, the figures being curved slightly to get the ends in the grooves. When the figure is released, they naturally spring into position. When all the figures are placed and evenly spaced the spaces at ends and between figures are filled by inserting blank strips to fit the spaces. Then the grooves are driven down flat against the ends of the figures and the number is ready for placing in the lamp.

Will Re-manufacture Old Rubber

A plant has recently been incorporated in Milwaukee, Wis., under the name of Federal Rubber Co., to exploit a chemical discovery made by W. F. Koneman, of Chicago, a stockholder of the new concern, to manufacture new products from the old, or in other words, to restore the resiliency and life to worn-out rubber and make it again a usable article. The company is backed by fifteen wealthy men of Milwaukee, among them being C. F. Pfister, Geo. Brumder, W. F. Mayer, Fred. Vogel and the estate of the late Wm. Becker. They expect to start the erection of a $100,000 plant at Cudahy within a few weeks.

The Vacuum Oil Company, No. 29 Broadway, New York, advise us that in the recent Targa Florio Race, held in Sicily,

The "Ruff" Quick Detachable Clincher Rim

The Standard Detachable Rim Co., 42 Broadway, New York City, have placed on the market the "Ruff" Quick Detachable Clincher Rim, which is simply an ordinary clincher rim sawed in two crosswise so as to admit of its diameter being enlarged sufficiently to slip it over a plain wheel, with simple means of securing it in place. At the cut portion two blind lugs and connecting screws are provided, one on each side of the rim. In attaching the rim to the wheel all that is required is to slide the rim over the wheel, and then draw up the two screws with a screw-driver. The air pressure in the tire will help to make the screws draw up easy.

The "Ruff" Quick Detachable Clincher Rim.

The tire lugs are especially designed for these rims and called "Blind Lugs." They are provided with removable stems. The long stem is first used to hold the lug in place till the tire has been put on the rim, the tire is then partly inflated so as to hold the lugs in position when the long stem is removed and the short stem is screwed in its place; this leaves a perfectly smooth surface to the rim and no lug stems can be seen in the wheel.

Panther Wrapt Tread Clincher Tire

Electric Rubber Mfg. Co., of Rutherford, N. J., are now on the market with their Panther wrapt tread clincher tire, in which is used South Sea Island cotton fabric with Up-River Para gum between the plies wheel prevents the threads of the fabric from chafing each other. By a special process which they have perfected themselves the fabric is thoroly impregnated with rubber, causing them to adhere very closely and thus adding to the resiliency of the tire. These tires are made on the well-known wrapt tread principle by which, after the body of the tire is built up from the fabric, the different plies are covered with a layer of pure Para rubber about ⅛-inch thick, after which the tread of the tire, consisting of several layers of specially prepared and toughened material is wrapt under pressure to the body of the tire. The tire is then vulcanized by the slow live steam process. By this method of tire manufacture, the various layers of fabric lie perfectly smooth and are not squeezed out of alignment. This method also permits the application of a new tread after the old tread is worn down to the breaker strip, which lies between the tread and the body of the tire.

On the Panther tire, the core of the bead strip extends up beyond the point of pressure and therefore prevents rim cutting. The core is made of a special composition of their own compounding and is sufficiently elastic to bring the casing back to normal dimensions after stretching on the rim.

This concern is also manufacturing the Panther corrugated flat tread casing, which combines the good qualities of the regular casing, besides guarding against skidding on greasy or snowy pavements. They also make the Panther inner tubes in both gray and red.

Splitdorf in New and Larger Quarters

C. F. Splitdorf, the well-known New York manufacturer of ignition apparatus and electrical specialties, has moved his laboratory from 17-27 Vandewater street to 261-265 Walton avenue, corner of 138th street, Borough of Bronx.

Their new building, which has been designed and built especially for them, is of the latest fireproof construction and equipt with every modern appliance for the production of high-grade work. One important feature is the installation of the Edison breakdown service which can be thrown in at a moment's notice, thus insuring continuous and uninterrupted work. Each department is equipt with time-saving devices and the most modern machinery.

The entire building, which contains over 50,000 square feet of floor space, will be occupied solely by the Splitdorf Laboratory.

The dynamo-dynamometers, for testing automobile engines, which have been supplied by Joseph Tracy to a number of leading builders, will in future be marketed by the Sprague Electric Company under an arrangement by which Mr. Tracy will supervise the construction of the apparatus at their factory.

The Warner Instrument Co., Beloit, Wis., have built an exact working model of the regular Auto Meter of mammoth size. It is 9½ feet in height; the head of the instrument is 4 feet in diameter and has a scale 10½ feet in length, weight about 800 lbs. The instrument is entirely covered with gold leaf so as to protect it from the weather, as the instrument will be subjected to all kinds on account of the extensive tours it will make. It is mounted on a car with a special body and is now being demonstrated on the thorofares of the principal cities of the country.

grade black leather finish, whipcord back 3-ply auto cloth, bows of selected second growth ash, hand-forged joints and body irons, three side curtains on each side having large light in each one, and a roll up back curtain having a light 10x18 inches.

They also make a three-piece detachable storm front, with extra large lights in each side, front piece with two lights 20x28 inches, made to roll up and fasten under front bow, making a ready and serviceable wind shield when desired. A curtain bag is furnished to keep the curtains in when not in use. This front complete with all irons and fasteners to attach to cars lists at $80, for Mackintosh, and $100 for Pantasote.

The runabout tops are made of same materials and high-class construction as the touring car styles. The price of a 3-bow top, strap style complete with all irons and fasteners to attach to cars, is $44 in Mackintosh cloth and $52.50 in Pantasote.

Racine tire covers are made in black enamel duck or in black, red, green or tan imitation leather.

The Simplex all-brass folding glass front is hinged about one-third down from top. It is held in open position by stays which telescope by simply loosening nut at bottom of rod. The list price is $60, with ¼ inch plate glass, ready to attach to car.

The "Robbins" Touring Car Top

Irvin Robbins & Co., 32 East Georgia street, Indianapolis, Ind., are offering to the trade what they claim to be a thoroly up-to-date touring car top made with leather, covered bent auto bow sockets, eight outside joints, six straps, and goose necks to fit the body. The covering is of heavy imitation leather, lined with broadcloth, and fitted

The "Robbins" Touring Car Top.

with removable storm front in three pieces, with celluloid in all curtains.

When the top is not in use it can be folded up and strapped flat, and covered with a dust cover. The builders furnish measurement diagrams, by the use of which they guarantee that their tops will fit any machine yet constructed without any further

price of No. 1 is $7.00; No. 2 $9.50 and No. 3 $12.00, with a liberal discount dealers.

The "P. M. S." Tail Lamp.

"P. M. S." Generator, No. 1.

The P. M. S. tail lamp burns kerosene and sells for $2.75 each.

They also make the P. M. S. vulcaniz outfit. This is one of the conventional repair outfits which is put up in a sm wooden box, consisting of ¼ pint of a cure, ¼ pint rubber cement, piece of sa paper, emery paper and 2 brushes. T outfit retails complete at $1.00.

"Auto-Shine"

The "Auto-Shine" Polish Company, Buffalo, N. Y., manufactures a high gra varnish polish which is compounded es cially for automobile work and is the vention of a practical painter of forty yea experience in the finishing of the high class of carriages.

This preparation cannot injure the fin finish because it contains no solid matter any kind. The makers claim that it will pit the surface; contains no gums or otl sticky substance; will not stain a white other light colored finish and will not coll dust. It removes hand marks and grea spots and restores the original lustre w little effort.

It has been used two seasons by the R. Thomas Motor Co., and the Buffalo A tomobile Station Co., to the exclusion of other varnish polishes.

The preparation is called Auto-Shine a is put up in quantities from ¼ pint to 1 g lon. On receipt of 5 cents postage, t company will send a generous sample, lar enough to polish the average size touri car. Prices range from 25 cents for a qua ter pint, to $3 for a gallon. The manufa turers will pay expressage on trial orde

lower speed engine, giving little vibra- and minimum weight. At present they making these sets in two sizes, viz.: 2 H. ize, 15x33x24 inches high, weight 370

tank to be connected for water connection

The "Richardson" automatic storage ba tery charging swith is used to make con nection automatically between the generato or source of current, and the storage ba tery only when the voltage is high enoug to charge the battery, and to disconnect th circuit automatically when the voltage fal too low. Each switch is furnished for spe cific voltage, or for charging a specific num ber of cells of storage battery, and must b ordered and used for that number only. A series coil is employed to assist the voltag selecting coil after the contact has been mad This insures a good strong contact, thus pre venting the burning of the clips. Each breake is provided with carbon contacts on eac side to take the arc when the circuit break altho the current at this time is so low a to reduce this arcing to a minimum. Ad justments are provided on the bottom o the breaker so that it may be set to releas within certain reasonable limits of voltag and current, also an adjustment at the to for limiting the pull of the breaker. The con tacts which carry current are a special sprin bronze, with a maximum carrying capacit long life, and in their larger circuit break ers are made up in units. The very larg breakers furnished for heavy currents consis of two coils, one coil operates the large one, which carries the heavy arm conduc ing the current. These contacts are mad of especially constructed spring clips o heavy bronze, the proper number of clip being added according to the current. Th machine is of handsome design, full polishe copper, with the exception of the coil, whic is covered with a waterproof material re sembling leather. The switch is mounted o an enameled slate base, with connection and terminals marked, all ready for mount ing, either with or without the base. Its lis price is $20.00 for any amperage capacity u to fifteen and any voltage.

Owing to the promotion of Mr. H. F Field to position of sales manager of th Hartford Rubber Works Company, the po sition of branch manager at Detroit wa left vacant, and Mr. C. W. Hatch, formerl with the Diamond Chain and Manufac turing Company, has been appointed t the position of local manager at Detroit.

In the recent Automobile Endurance Derby at Point Breeze, the winning Auto car had its rear wheels equipt with Hart ford Midgley tread Dunlop tires. Thes tires are claimed to have been used 3,00 miles before entering the race, but notwith

purposes.

When the generator valve is applied to
crankcase of a two-cycle engine, it com-
es both the functions of a carburetor and
usual check valve placed between it
the crankcase. Its operation is depend-
upon the alternate periods of pressure
partial vacuum existing in the crank-
e at different periods of the cycles.

The "Radio-Escape"

The Globe Machine & Stamping Co., 3950
milton Ave., Cleveland, Ohio, are manu-
turing and marketing the Radio-Escape,
styles of which are here shown.

The "Radio-Escape," Type A.

The object of the device is to save the cool-
liquid in gasoline automobiles, summer
winter. In winter it retains the vapor

new or old—it simply consists in sealing t
radiator by closing the overflow aud scre
ing on the Radio-Escape in place of the c
at the top.

The "Radio-Escape," Type B.

The escape is of the safety-valve princi
and is set to release at 10 pounds, and as t
average sealed radiator pressure is mu
less than this, it prevents the radiator fr
being strained or exploded.

The device can either be set into the ra
iator cap, as in type A, or can be appli
by drilling and tapping the radiator cap a
screwing in Radio-Escape Type B.

Heerman's 4-Cylinder, 2-Cycle Motor

HUGH DOLNAR.

This motor was designed by Mr. T. W. Heermans, Consulting Engineer, 617 Chamber of Commerce Building, Chicago, Ill. The design is with a view to compactness, simplicity, and uniform torque, or crank-shaft turning impulse. The motor has four 2-cycle cylinders, water-cooled, 5¼ in. bore by 5 5-16 in. stroke.

The cylinders are cast in single units with integral water-jackets, and are fixt in opposed pairs to an open frame which has a charge intake passage open to the carburetor, and two charge compression chambers and two automatic charge intake valves at each end. The two charge intake passages are connected by a two branch supply pipe to the elevated carburetor, not shown, fixt to the branch pipe at A.

The pistons have central charge intake nozzles, opening toward the cylinder heads, and the exhaust ports, 2 in number, are in a plane above the 2-cylinder intake-ports, as clearly shown in the sectional elevation at F1, Fig. 1. Fig. 2 is the motor end elevation and Fig. 3 is a vertical section of a piston showing the cored intake passage.

The two pistons for each opposed pair of cylinders are fixt to the opposite ends of one vertical piston rod, so that both piston strokes are made against charge-compression in each of the two pairs of cylinders Each piston rod has a yoke with a rectangular opening in the middle, and these yokes take sliding pin-boxes, thru which pins pass to take the two ends of a double bell-crank, BC, BC, BC, Fig. 1. The middle point of the top member of this bell-crank is carried on a pin which is fixt in a cylindrical, vertically-sliding guide, fitted to a bored seat in the motor frame to which the cylinders are fixt. The lower member of BC is a capt wrist-box, fitted to the crank-wrist of the single throw crank-shaft, which is 1⅞ in. radius, but may be of any desired radius. The double bell-crank, BC, is two similar members, so as to make forks at each of its 3 extremities, the ends of the top member taking the piston rod block pins while the fork in the lower member of BC takes the bronze, split, crank-wrist box.

Fig. 1. Heermans' 4-cylinder, 2-cycle motor. Front elevation, in partial vertical section.

This linkage forces one pair of pistons to move upward when the other pair moves downward, and, as before stated, cushions the piston at each end of travel on the comprest cylinder-charge.

Fig. 2 shows the small fly-wheel with a built-in, two-ball governor at the right, while the section at the left shows the intake

chamber, D, open to the carburetor, and the compression chamber, E, in which the charge for the top cylinder is comprest, and the compression chamber, E1, in which the charge for the bottom cylinder is comprest.

The governor is connected to a sliding-sleeve throttle valve. In this drawing the crank-shaft axis is 9⅜ ins. below the mid-plane of the motor-frame to the top and bottom of which the cylinders are fixt, and the vertical measurement is 21 ins. from one cylinder head to the other, or 42 ins. over all, bolt heads included. There are 2 intake ports and 2 exhaust ports, in different planes and in different quadrants of the cylinder bore. The exhaust ports are 1¼ ins. long, intake-ports 13-16 ins., measured parallel to the axis of the cylinder, and the vertical measurement of the ports, outside to outside, or from top to bottom, is 2⅞ ins. F1, Fig. 1, is the exhaust chamber of one cylinder, open to the two exhaust ports and also to the four-branch exhaust pipe, F F, Fig. 2.

Fig. 2. Side of Heermans 4-cylinder, 2-cycle motor, automatic compression chamber valves, and passage from carburetor in section.

OPERATION.

When one pair of pistons move upward the top piston is compressing a charge while the bottom piston is being driven by a fired charge. Since there are four pistons, two of these pistons are always being driven by fired charges, and two of them are always compressing charges. The double bell-crank between the pistons and the single crank transfers working piston pressure to the crank, beginning at intervals of 90 degrees of crank pin angular advance, so that except for the loss of pressure when the exhaust ports are uncovered, 720 degrees of angular advance impulse are delivered to the crank pin during each revolution, or 360 degrees of angular crank advance, making the torque as nearly uniform as that given to the 8-throw crank-shaft by eight 4-cycle cylinders.

ADVANTAGES.

One of the greatest faults of the trunk gas engine, is the uncushioned piston stroke. In the 4-cycle motor 3 of the 4 piston strokes of each cycle end against no piston resistance, and only the compression stroke, ends against a resistance, due to the charge. All uncushioned piston strokes must have the piston and rod momentum resisted and absorbed by the crank-pin, which must also start and accelerate the rod and piston in the next stroke. In slow speed engines this fault does not lead to serious working losses, but in small, high-speed motors the piston and rod must be made as light as possible to avoid loss of power in piston and rod acceleration and retardation.

This is the first gas engine noted by the writer in which every piston stroke is cushioned, so that piston and rod momentum is taken up by useful work in charge compression, instead of having to be wastefully overcome by crank and flywheel momentum

HARTFORD MIDGLEY TREAD TIRE

Clincher or Dunlop

Successful, Safe, Sound and Sightly

¶ From these pictures you'll get a good idea of the tire that has created a veritable sensation in all Motordom.

¶ Eminent experts like Hiram Percy Maxim, Henry Souther, Herbert Lyttle, Owners who drive, Drivers of Track, Road and Endurance Contests, Chauffeurs—all agree that it's the greatest tire invention of the age.

¶ Think what it means to buy a tire—**a tire mind you**—not a separate device—that will **never** slip or skid, even on ice. Think of 200 little spikes—**like cat's claws**, in each tire—that grip the ground continuously, yet that detract not one whit from **fastness or resiliency.**

¶ Why be satisfied with any other tire equipment? Act **now.** Insure the safety of your car and its occupants by putting on Hartford Midgley Tread Clincher or Dunlop Tires. Better have MIDGLEY UNIVERSAL RIMS, too. You can then use Clincher or Dunlop Tires at your option.

Millimeter Sizes for Foreign Cars

PISTON SIDE THRUST.

The second fault of the trunk gas engine in kinetic importance, is the piston side-thrust due to connecting rod angle. The vertical motor, ordinary form, is higher than is desirable, and the rod is shortened to the utmost permissible extent, to reduce the motor height as much as may be. Two piston strokes is about the maximum rod-length practice, and this gives a heavy side pressure on the piston.

Fig. 3. Piston of Heermans' Engine.

In the motor in question the piston side thrust is almost wholly eliminated. The squared pinblocks have only a small cross-travel in the piston rod yokes, and as these pinblocks can have ample surface and can readily be made self-lubricating and can be encased and dust-proof, the side-thrust on the piston rod is reduced to a negligible factor.

NUMBER OF CRANKS.

By this construction there is but one throw for 4 cylinders, and the double bell-crank makes this one crank the exact equivalent of a four throw crank-shaft in impulse distribution of the ordinary form of motor.

NUMBER OF SLIDING SURFACES.

Counting crank-shaft bearings as equal in area and frictional resistance, and piston and cylinder friction as also the same in the ordinary motor as in Heermans' motor, tho in both these friction-producing element combinations the advantages are largely in favor of the Heermans motor, there remain 4 joints in the Heermans engine as against 8 joints, two for each connecting rod, in a 4-cylinder motor, ordinary form. Heermans' motor has two sliding surfaces and two pin-bearings which do not appear in the ordinary motor, but these have very slight travels and correspondingly small friction losses, and are offset by the saving in piston and cylinder friction.

DIMENSIONS AND WEIGHT.

The 4-cylinder motor, cylinders 5¼x 5 5-16 ins., requires 42 ins., height, 33½ ins. width, and 24 ins. in length, which is a saving in length over that of an ordinary 4-cylinder vertical, 5 ins. dia. motor, but is considerably higher than the usual type. The weight is about the same as a 4-cylinder motor of equal bore and stroke, and theoretically should give a notably greater horsepower than those of ordinary form

To sum up, this motor is small, has a single throw crank-shaft, develops small internal friction, is simple and easy to build, and has but one joint, that on the crank pin, subjected to severe duty, and this bearing is of such very large dimensions that it should wear well, there should be but little wear on the cylinder walls, as there is almost no side thrust, and every bearing is amply supported on both sides. The torque is better than in anything 4-cycle with less than 8 cylinders, and the motor has no valves save the four very light compression chamber intake-valves, which are cold, and work under no pressure at all, save that of a light closing spring.

COST.

This is an extremely cheap motor to build, its forms and dimensions being all highly suitable for repetition tool machining, and call for but little hand fitting at any point.

The Police and Fire Commissioners of Grand Rapids, Mich., have so hampered the demonstrating of Austin Cars by severe insistence on unreasonable speed limits, that the manufacturers, Austin Auto Co., are strongly inclined to move their plant to Detroit, Mich.

Beginning next fall, automobiling will be included in the manual training course of the Washington University, according to a plan suggested by Dean C. M. Woodward and backed by Samuel Cupples, who has promised to donate one or two machines as a part of the equipment. The student will be taught all about the automobiles—how to build, repair and run them.

At the annual meeting of the Automobile Club of Cincinnati the following officers were elected: President, Val Duttenhofer; first vice president, Dr. A. B. Hyl; second vice president, F. N. Temple; secretary, Dr. L. S. Colter; treasurer, C. Gordon Neff.

In addition to the factory testing crew Pope Motor Car Co., Toledo, Ohio, also employ a testing crew under the direction of the sales department, so that every Pope Toledo car after being tuned up to perfect operation by the factory crew, is taken in hand by the sales department crew who are naturally determined to have the car right. In the final inspection after the body has been fitted, etc., the sales department is also represented.

the strangling valve (Q), thereby causi a partial vacuum in the mixing chaml (A), accordingly, thereby lifting the quired amount of gasoline from the spr nozzle (U), to give the proper mixtu As the speed of the motor is increas and more fuel required, the increased va uum automatically opens the automa air valve (L), and so supplies the nec sary additional air, thus automatica maintaining a perfect explosive mixture

Re-Charging Tire-Filling Tanks

We have received from P. C. Avery, Milwaukee, Wis., a complete explanation how to charge tire-filling tanks from t large drums of liquid carbonic acid g which can be purchased from any one a dozen concerns in this country. T sizes of these drums are furnished, of and 50 pounds capacity respectively.

To fill small tank proceed as follov Turn the large drum of gas, bottom e up, with the valve down; support it on t wall by means of a strap or band of ir so that the valve will be about three f from the floor, which is a handy distance

Use three or four feet of 20-gauge inch brass or copper tubing to connect t large gas drum and the tire tank. The t tank should be set in a large bucket

WOODWORTH

DETACHABLE **TREAD** ADJUSTABLE

Tires Protected with Woodworth Treads Cannot be Punctured

Punctures and other Tire Troubles that cause wayside Delays are not only Costly but Unnecessary. They can be Avoided. The pneumatic tire is made of rubber; a substance too tender to withstand the hard usage to which it is subjected. It is not tough and cannot last long however careful the running. The Woodworth Tread Protects the Pneumatic Tire Precisely as a Shoe Protects the Foot. It Bears all the hard knocks, roughs and scuffs, wear and tear of rocky roads, rutty roads, slippery roads, muddy roads, sandy roads and all kinds of roads. It does More to Make the Running of an Automobile Safe and Economical than All Other Devices ever Invented for the Purpose. It has Saved Thousands of Tires from Punctures, Prevented Thousands of Accidents, Saved Many a Car from Demolition, Saved Many a Life and May Save Yours. Write to-day for booklet, "Safe & Sane Automobiling." Sizes and prices as follows:

immediate attachment to the dash. The have met with enthusiastic approval fro those who have been shown samples a the prospects are for a very large use these mouldings on 1908 cars.

"J.-M." Asbestos Motor Cement

This cement is made of asbestos and wh applied forms a fireproof covering on heat surfaces of all kinds. It is made by H. W Johns-Manville Co., 100 William street, Ne York city, and is especially adapted for coa ing automobile and marine motors, muffle etc., to prevent surroundings from catchi fire and to keep discomforting heat from pa sengers.

This cement is easily applied, is very a hesive and will withstand vibration. It put up in five-pound packages, listing at cents each, with discount to the trade.

The American Die Casting Co.

The American Die Casting Company, Indianapolis, Ind., was duly organized a incorporated in Indianapolis, Indiana, February 1st, 1907. This company mak a specialty of die-casting bearings a other parts, and they produce castings all bearing metals, including all whi metals, babbitts, white brasses a bronzes, on the market. These castin are smooth and true, and are cast to a tual finished size, hence they need no m chining.

They guarantee the composition of t castings thus produced to contain the sa percentage of alloy as in the original b or the metal furnished. By this proce the shrinkage or loss is almost eliminate and in no case does the shrinkage or lo exceed five per cent. of the net weight.

A die made for one kind of metal them will cast any of the bearing met on the market with true surface and f ished to size without machining. T company makes the dies on such ter that the cost of the dies is wholly eli inated.

THREE BIG THINGS
Accomplished for the Motorist

A LONG-LIVED TIRE—

Morgan & Wright Tires are made of extremely tough rubber stock; the fabri (the best quality obtainable) is utilized in a manner that greatly enhances it normal strength, and the *shape* of the completed tire is such as to give it the leas possible strain when inflated. The result (proven by the experience of hundred of motorists) is a tire that *can* and *does* stand a tremendous amount of hard usage

AN ANTI-SKIDDING DEVICE—

The Midgley Tread is wholly unlike any other device offered to motorists fo the same purpose. The four endless spiral wires (firmly vulcanized into th rubber) are not only effective on a *new* tire, but become *increasingly* so as th tread wears down—which is emphatically *not* the case with any other device The fact that this tread is not an attachment, but *a part of the tire*, is also a stron point in its favor, and one much appreciated by motorists.

A SAFE AND CONVENIENT DETACHABLE RIM—

The Midgley Universal Rim is unquestionably the most used rim on the mar ket. It is the *only* rim that will satisfactorily accommodate either Clincher o Dunlop tires with the *same set* of beads (Midgley beads have only to be reverse to change from one style to the other). Above illustration shows position o bead for Dunlop tire; also the turnbuckle fastening and the operating wrench In addition to its simplicity of operation, this rim has the added (and ver essential) virtue of being an absolutely *safe* rim to use.

Trade Printed Matter

The small tool department of the Pratt & Whitney Co., Hartford, Conn., have just issued its catalog No. 4, covering taps, dies, milling cutters, drills, lathe tools, reamers, punches, special tools, etc., and the catalog is notable for the clearness of the illustrations and its generally excellent appearance as well as for the very ample data contained in it. Besides descriptive data on the tools illustrated, it contains tables of various gages, weights, etc., useful to users of these tools. It is fully indexed.

A neat folder has just been issued by the Peerless Motor Car Company, Cleveland, Ohio, with eight finely engraved plates of Model 15, forty-five horse power and Model 16, thirty horse power 1907 Peerless cars. These represent the eight principal types of modern motor car, the open four and seven-passenger touring car, the racy style of roadster, Limousine coupe, cape top roadster, Berline and demi-limousine body and hansom. The brochure is so arranged that it unfolds to make a very neat picture framed or otherwise that will add to the artistic appearance of an office or elsewhere.

The security of Fisk mechanically fastened automobile tires is the theme of a booklet recently issued by Fisk Rubber Co., Chicopee Falls, Mass. A number of pages contain fac simile reproductions of newspaper articles on automobile accidents resulting from tires coming off rims. The point that Fisk tires cannot come off accidentally is strongly brought to the attention of the reader.

Quite a handsome booklet has recently been issued by Firestone Tire and Rubber Co., of Akron, Ohio, descriptive of their pneumatic tires. Besides being good looking, this booklet has a ring of practicability that makes it attractive from a common sense point of view. From the first paragraph, explaining that the data in the booklet has been prepared by practical men to the final statement that "the factory is back of each branch and repair shop" the booklet appeals to one's reason and common sense.

An elegant catalog, a fitting introduction for an elegant instrument, has lately been issued by Stewart & Clark Mfg. Co., 502-520 Diversey Boulevard, Chicago, exploiting the 1908 Stewart Speedometer. It is printed on fine enameled paper on which the well made half-tone engravings have made clear, attractive illustrations, and not only the appearance, but the contents of this catalog leave a most favorable impression on the mind of a recipient. Strong arguments are offered in support of the type of mechanism used and each detail of construction is fully explained so that the reader gets a very clear idea of the reason for every step in the designing and constructing of Stewart Speedometers.

In the latest folder sent to tire dealers by Goodyear Tire and Rubber Co., Akron, Ohio, they make use of card terms and use playing cards in the cover illustration. The folder is, as they put it, is their "show down" and they very forcibly prove that they hold a good hand and that the dealer will hold a good hand if he handles Goodyear tires. One very convincing point brought out is the fact that Goodyear replacements amount to 1.41 per cent.

The catalog of the Union Supply Co., of Toledo, O., is very convincing and substantial evidence that the first-class, hustling, up-to-date jobbers of automobile material are not all located in the East. The catalog they issue contains about 100 pages and as a good, heavy paper is used the book is quite thick and substantial looking. The compilers have shown good sense in using good white paper, good illustrations (and lots of them), and in employing a first-class printer, so that altogether from a typographical point of view and from a ultilitarian point of view the book is a first-class job and not only reflects credit on the company and goods it advertises, but makes the sort of impression on a reader that a seller wants to make on a prospective buyer. The manufacturers whose goods are listed in it are fortunate.

The latest catalog of the Acme Motor Car Co., of Reading, Pa., is printed on stiff tinted paper and the cover design is an artistic poster effect showing a motorist pressing a horn bulb while out of the horn comes a blast of favorable sentiment anent the Acme cars. The illustrative scheme includes a novelty in a picture entitled "A Mid-Winter Night's Dream," showing an Acme car in moonlit, mid-winter scenery.

"A Past Performance" is the title of a book issued for the Jones Speedometer, by Mr. John B. Rowland, of Publicity Press, New York City. As the title indicates it deals with something which has gone by and not to come, and each page is brimful of entertaining matter. It is the summary of the events which transpired at the housewarming of the new Jones Speedometer building at New Rochelle, on the night of November 18 last, and judging by the illustrations, descriptions, stories and testimonials, it was a night long to be remembered with great pleasure by those who were fortunate enuf to have attended. The book devotes itself primarily to the entertainment which took place at "Forty-five Minutes from Broadway," and altho it is issued as an advertisement for the Jones Speedometer, it is humorous enuf to be sold as a book of wit. Copies can be had free by writing to the Jones Speedometer for their booklet entitled "A Past Performance."

The Automobile Owners' Supply Depot, 1655 Broadway, N. Y., established last year, have issued a catalog of pretentious size and attractive style. The index, which covers all leading accessories, is on the inside front cover inviting one to immediately search for the particular accessories uppermost in one's mind. The catalog is not elaborate, but a very good effect has been secured by the use of clear illustrations and a tasteful arrangement of the same on the pages.

The White Company, Cleveland, Ohio, have just issued the third of its admirable series of route books, which are for free distribution to all tourists. This new issue is devoted to the main touring route between New York and Boston. Complete and accurate road directions are given for traveling over this important route in either direction. The route directions are copiously illustrated, and, in addition, there is a fine double-page map. Copies of White Route Book No. 3, and of the two previous issues, may be obtained on application to The White Company, or to any of its branches or agencies.

Jos. N. Smith & Co., Detroit, Mich., have issued a new 48-page catalog of new, high-grade metal trimmings, etc., for the 1908 trade, and are sending it to the automobile trade in envelopes that are marked: "Don't throw me away, if not wanted to-day; because you'll need me to-morrow."

The latest catalog of the Motor Car Equipment Co., 55 Warren street, N. Y., is, as it purports to be, an encyclopedia of high-grade automobile accessories. It is also a common sense catalog containing plain advice regarding methods of ordering, a caution about prices, a very ample index and other common sense features that appeal to the practical. The company has also shown common sense in having the catalog printed in good style and in using good, white paper on which the illustrations show up to good advantage.

A neat little booklet has just been issued by The Lunkenheimer Co., of Cincinnati, Ohio, to advertise the merits of their generator valves. It is printed in red and black and the cover illustration comprises a half-tone one of the valves surrounded by a conventional design. Both exterior and interior views of each model are shown and the descriptive data given is very complete.

The Diamond Chain and Mfg. Co., Indianapolis, Ind., has issued an instructive treatise on power chains and sprockets. In addition to listing their complete line of automobile, bicycle and motor cycle chains, it gives much information on the manufacture and use of the machined chain. The chapter on power transmission explains the advantages of chain gearing, and draws comparison with belting, bevel gears, etc. It gives instructions and tables of sprocket dimensions which enable any manufacturer to cut the sprockets in his own shops, or test the accuracy of sprockets bought outside. The chapter on care of chains includes good, practical hints which should help any user to get the most and best service from his chains.

Indestructible Steel Wheel Co., 1303 Michigan Ave., Chicago, Ill., taking full advantage of the use of their wheels in an automobile somersault stunt to advertise the great strength of their wheels. Ringling Bros., circus proprietors, are using "Indestructible" wheels on an automobile on which this stunt is performed in their show and they have written the manufacturers a strong testimonial letter which has been reproduced in a 4-page folder in conjunction with illustrations of the hair-raising performance. The folder is being mailed to the automobile trade.

FUELS FOR EXPLOSIVE MOTORS.

This is the title of a pamphlet of 20 pages and cover recently published for private distribution by Maxwell-Briscoe Motor Co., of Tarrytown, N. Y., because of the numerous requests received for an account of the fuel test they recently conducted with three Maxwell cars running on gasoline, alcohol and kerosene, respectively. The pamphlet has been compiled by A. B. Barkman, who has gone into an exhaustive technical treatment of the subject of fuels for explosive motors, working in where most appropriate references to the practical results obtained in the Maxwell test. The matter in this pamphlet, which is 6x9, is set solid in 8-point type and the 20 pages contains immensely more data than would be supposed. As it has all been carefully compiled and is strictly correct, technically, the pamphlet is of value to all persons interested in fuel economy and both the Maxwell Co. and Mr. Barkman deserve the gratitude of the automobile trade for this contribution to the literature of the industry.

A line of coupes especially for the use of physicians is nearing completion in the Winton factory at Cleveland. The body is modeled after the coupe that Mr. Winton has had in his personal service for more than a year. It incloses the steering wheel, the dash and its equipment and the seats, affording the fullest protection from the weather to driver and passenger.

THE MODEL FRICTION ELIMINATOR FOR BEARINGS IN THE CONSTRUCTION OF HIGH GRADE MOTOR CARS AND MOTOR BOATS IS

AUTOMOBILE BRAND PLASTIC BRONZE

BECAUSE UNDER ALL CONDITIONS IT STANDS THE GREATEST AMOUNT OF USE AND HEAT WITH THE SMALLEST POSSIBLE WEAR AND FRICTION.

ARDMORE, PA., May 28th, 1907.

IGHT MFG. & FOUNDRY CO., Pottstown, Pa.

Gentlemen:—The motor in the car with which we won the 24 Hour Track Championship at Point Breez
May 24th and 25th, was equipped with plastic bronze bearings. We did not have the slightest trouble wit
r bearings throughout the race. The motor ran perfectly cool throughout the entire contest, and at the en
the 24 hours, in which time we covered 791 miles, there was not the slightest slack in any of these bearings
I think this speaks very highly for plastic bronze and I assure you that we will continue to use it unt
e find something better, which now seems impossible.
Thanking you for your many courtesies, we remain, Yours very truly,

THE AUTOCAR CO.

This bronze has been developed from necessity and its results have made it famou
rings are too important to be made of an inferior or experimental metal. We have dev

Dealers' Department

Helpful Hints

By A. D. Hard, M. E., Marshall, Minn.

A great many automobile manufacturers have their nuts so loosely put on that the first turn of the wrench will render them easily turned off with the fingers. This is inexcusably bad workmanship, and is the cause of many losses on the road that lead to injury to working parts. Another common neglect is not using cotter pins where they are called for. All burrs (or nuts as they are commonly called) that have any chance to rattle loose from the vibration of the motor should be crown nuts with thin steel washers to adjust them to the holes for the cotter pins to retain in place. There is no form of nut-locking so far discovered that is as effective as this. In the car that I am now using I have replaced some twenty-two plain burrs with crown burrs having these steel washers and cotter pins to retain them in place, and I would not change back for ten times what the change cost me.

If you want to make your clincher tires last until the casing wears entirely out without punctures or blow-outs or rim-cuts you can do so easily. For a casing 3½ inches in diameter buy a 3-inch single tube automobile tire of the same wheel size, and cut it open all around on the inner diameter, and remove the retaining studs. Cut the tire in two and after putting it inside the clincher casing mark with a lead pencil where the ends lap. Take it out and cut off enough of the end which was marked to render the tire just one-half inch longer than the mark indicated. Replace the prepared tire in the clincher case and put in a 3-inch inner tube inside of the protecting inner tire, and put on your wheel and pump up. But before you put the inner tire in the casing it will be well to pare the edges of it to a bevel edge in order that it will not wear the inner tube. The place where the ends come together should be protected by a strip of heavy tire tape, or two or three thicknesses of ordinary tire tape in order to protect the inner tube from pinching between the ends. This plan does not involve as much expense as you might at first conclude. Single tube tires, second grade, can be had for $12 for 3x30 size, and you save some expense by using a smaller inner tube. I have found this plan very effective in making tires extremely durable and free from ordinary troubles. As long as tires are properly filled with air they do not undergo any very destructive injury by actual use, but as soon as they begin to go flat, and grind between the rim and the ground, they will rapidly progress toward destruction.

In adjusting a carbureter begin with the least amount of gasolene supply and the largest air supply and adjust up until proper power is obtained without sutting the spark plug.

A small amount of graphite of fine grain will add greatly to the lubricating effect of any oil. Do not use too much.

An ammeter used to test batteries will run down the battery power more in ten minutes' continuous attachment than the use of the batteries for thirty days running the spark plug.

If there was some way to lock the differential so that both drive wheels would pull as though the axle was solid we could frequently get out of mud holes without calling upon the clod-hopper with his team.

St. Louis Show, December 14-21

The St. Louis Automobile Manufacturers' and Dealers' Association recently organized with a membership of fifty-five, have decided to hold a show next December. Dates will be from December 14 to 21.

Omaha Dealers' Race

On Friday, May 26, an interesting race occurred between J. J. Deright driving a Stoddard-Dayton runabout, and H. E. Fredrickson, driving a Thomas forty. The race was over the Dodge street course. Fredrickson gave Deright three-eighths of a mile start, and caught him in three miles.

Both men are dealers in Omaha.

New York Automobile Trade Association Incorporates.

At the last meeting of the Board of Directors of the New York Automobile Trade Association, held in their new rooms in the Motor Mart, the matter of incorporation was completed and the Darracq Motor Car Company, Mr. C. B. Rice; The Haynes Automobile Company, A. G. Southworth Company and D. P. Michols & Company, were elected members. Other matters of importance to dealers in New York were discussed, such as an automobile sale week, the refusal of steamship companies to allow gasoline commercial motor trucks on their piers, and the establishment of a collection department for the benefit of the members.

The first endurance run undertaken by the California Automobile Dealers' Association took place on May 20, proving a success from start to finish. Of the thirty-four cars that participated in the run fifteen cars came thru with perfect scores.

Thomas B. Jeffery & Company

Philadelphia Branch.

The Rambler salesrooms, 207-9 North Broad, occupy a 3-story and basement brick building, 45x125 feet, built and owned by the Jeffery Company. The main floor is decorated with potted palms and festoons of autumn foliage, and the walls are relieved by a well selected series of motoring water colors, making an agreeable interior, well calculated to produce a receptive frame of mind in callers of either sex.

Mr. W. F. Smith, general manager of this Jeffery Philadelphia Branch, said that it was the Rambler distributing agency for 11 Eastern and Southern States, and placed 500 cars, total valuation about $850,000 in 1906, and had already, April 26, 1907, handled 265 cars, value amounting to $350,000, and expected to place a total of about 600 cars, valued at about $900,000 during the current year.

The average price of the cars distributed by this agency, which handles the trade of Southern New York, New Jersey, Delaware, Maryland, District of Columbia, Virginia, West Virginia, North and South Carolina, Georgia and Florida, it is stated, is somewhat less than that of 1906 because of the great run on the new 1907 Rambler Model 21, fitted with an opposed cylinder motor, cylinder 5x6 ins., 20-22-H. P.

The Rambler Company makes a specially of a liberal treatment of purchasers, and promptness in shipping repairs and replacements for each and every component of any model, even the very old ones, at such individual prices as to actually total less than the retail price of the complete car. This is in strong contrast to the common practice of charging a much larger profit on repairs and replacements than on the completed car assembly, which high-priced practice finds some justification in the large handling costs of single component order filling. Each Rambler purchaser is supplied with a copy of the "Rambler Parts Price List," a 7x10 ins. book of 50 pages, containing the picture, number, code word and price of every component required to produce any Rambler car ever sold, with full instructions for ordering. The Philadelphia Branch has every one of these components in stock and readily accessible, and fills all orders the day received. This parts price list book is added to yearly, so as to keep it always as nearly up to the last factory productions as may be, and advance sheets are sent to agents with the first consignment of a new model, so as to give the purchaser every possibly facility in making repair and replacement orders. Prompt filling of orders for complete cars has also been a marked characteristic of the Rambler policy.

Of course, the great number of Ramblers now on the road gives the Jeffery designers every advantage of "trying out" in the hands of unskilled drivers, so that the things which cause delays are speedily discovered, and hence promptly improved to meet the originally unsuspected requirements of the problem.

In carrying out the details of the thoroughly systematized scheme of Rambler sales, printed matter as follows is used:

(a) A booklet, 32 pp. 3x6 ins., "Talking Points of Rambler Utility Cars, 1907." This book goes thru the 2-cylinder car components in detail, beginning with the chassis frames, and includes specific functional details, and all that the agent need say to the prospective purchaser.

(b) The same size booklet, 28 pp. Rambler 4-cylinder cars, equivalent matter.

Aluminum Alloys

from the best posted man in the country.
Read them carefully

THE HENRY SOUTHER ENGINEERING CO.

Hartford, Conn., June 5, 1907.

Syracuse Aluminum & Bronze Company,
Syracuse, N. Y.

Gentlemen:—

Referring to your letter of May 18th, the test specimens you sent for our Endurance machine shows the following results.

ANALYSIS

Sample	Mark	Manganese	Copper	Aluminum	Zinc
37261	$\frac{3}{70}$ Endurance Specimen	0.11 per cent.	7.84 per cent.	92.05 per cent.	None
37262	$\frac{7}{800}$ "	Trace	0.34 per cent.	83.42 per cent.	16.24 per cent.

ENDURANCE

Sample	Mark	REVOLUTIONS No 1 End	No. 2 End
37261	$\frac{3}{70}$—Endurance Specimen	558,600	816,500
37262	$\frac{7}{800}$ " "	1,550,400	1,618,300

Referring to the above results: To properly understand them, it must be understood that the load was exactly the same in both cases—30 lbs.—and that it produced a fibre of 10,600 lbs. per sq. in., and a deflection of .06".

It is apparent that the alloy containing zinc has double the endurance of the one containing copper. I will further state that these are MOST EXCELLENT results for aluminum alloys, as compared with others tested by us.

Very respectfully,
THE HENRY SOUTHER ENGINEERING CO.
(Signed)
Henry Souther.

Sample 37261 is No. 12 Aluminum
Sample 37262 is OUR ALLOY

The above shows that we know what we are doing.

You cannot afford to use anything but the BEST and the only place to get it is from the

SYRACUSE ALUMINUM & BRONZE COMPANY

530 Leavenworth Avenue, Syracuse, N. Y.

Hosted by Google

nal car stories and car advertising gave the largest percentage of tangible results, which is noted with much pride on the part of this publication.

This form (c), like all the other card forms, save in color, is 3x5 ins. stiff index card, pale yellow, printed in black, copy of genuine entries here given. A considerable proportion of the Rambler sales come from information recorded on their index card forms (c).

Upon sale, the purchaser's name, address and particulars are entered on index card for (d), which is the sales record, and is also a record of prospective buyer's information.

Index card forms (c) and (d), with filing cabinets to suit, are supplied to each agent, who is constantly importuned to give prospective purchaser information.

Card form (f) for names of possible purchasers, is also supplied to agents with filing cabinet to suit.

Card form (g). Every Rambler agent is supplied with form (g) and file, and the same form is filed by all principal agents and by the Kenosha Factory, making 3 duplications of each form (g) card filed in 3 different places. Upon this card is kept a record of all changes of ownership of each car sold.

A new card form (h) has just been sent out to Jeffery agents, as a suggestion for trial. This card is a more complete and comprehensive prospective purchaser form than before used. It has been sent to the agents with a letter saying that a different colored card is to be used for each different model, and that this form (h), is a "suggestion," which looks good and is to be tried out.

The card forms given are of interest, and are the most complete yet seen by the writer.

To sum up, the sales of this company are dependent, first, on good cars at very moderate prices, meeting the requirements of middle class purchasers. Second, on solicitous attention to keeping cars sold in satisfactory condition, so that they can be on the road all the time, and thirdly, on the good-will and consequent voluntary commendation of satisfied purchasers and users.

We are now located in our new fire-proof factory building and believe we have t finest chain plant in existence. We are not at this date, (June 1, 1907,) fully settled ar organized in our new quarters but are making rapid progress and can soon show result

During the past year we have invested a very large sum for the improvement conditions and methods and when our new apparatus is in full operation we will mak further gains in quality and efficiency.

We have provided for a large increase in output being determined to please all cu tomers on delivery. This we have found impossible in the past, as the demand fo "Whitney" Chains has kept steadily ahead of our capacity at our old plant.

During the past year we have made many important experiments and we can assur you we have not been asleep. Customers who continue with "Whitney" Chains are n likely to regret it.

Our 1908 models will be ready August 1, 1907, which date marks the beginning the new chain season. 1908 price sheets will also be ready on August 1st.

Retail Notes

Acme Motor Car Company, of Reading, Pa., upon reorganization, appointed Theodore E. Schultz, at 1843 Broadway, New York, as agent for that territory.

Automobile Import Co., 90-96 Stanley street, Montreal, Can., will represent the Reo car in the future.

Auburn Automobile Company, of Auburn, Ind., have started the erection of their new garage, at the corner of Green and Water streets. The building will be one-story, 180 by 60 feet.

Aerocar Company's Cleveland, O., branch has been discontinued and the agency for the car placed in the hands of the American Auto Co., which has opened a large two-story garage.

Allegheny Automobile Co., recently incorporated, has opened its new garage at 915-917-919 Irwin ave., Allegheny, Pa.

Automobile Equipment Company, occupying the basement of the Quaker City Automobile Co., 138-140 North Broad street, and Frank M. Bell, located at 324 North Broad street, are two new supply and accessory houses which recently made their debut in Philadelphia.

Brachem & Son, R. H., have leased for a term of years the garage on Fleet street, Manchester, N. H. The garage will accommodate over 100 cars.

Buckeye Garage, of Zanesville, O., will erect a handsome one-story brick and concrete garage on Eighth street, that place.

Bangor Auto Garage, located at Bangor, Northampton County, Pa., is a new garage recently opened at that place by Mr. Pearce, who recently received the agency for the Rambler in that county.

Buffalo-Carburetor Co., Albany, N. Y., has increased its capital stock from $10,000 to $20,000.

Buyte, Coates & Campbell Co., the San Francisco, Cal., jobbers have established a branch in New York City, with temporary headquarters at 35 Warren street.

Borough Automobile Co., on Palmetto street, near Bushwick avenue, Brooklyn, N. Y., will represent the Haynes car.

Brown, W. J., of Wellman, Ia., will handle the Glide cars in Washington and Keokuk counties.

Brazille Automobile Co., of St. Paul, Minn., have recently made their debut in the auto business, having secured the agency for Stevens-Duryea, Buick, Autocar and Baker electrics. They located in their new garage April 1, at 15 East Ninth street.

Clark Automobile Co., E. R., located at 117-119 Lyman street, Springfield, Mass., will occupy, when completed, the new two-story fireproof garage being erected at 238 Maple street, same city.

Costa, M. J., with a number of others have formed the M. J. Costa Motor Car Co., and have located at 2117-2121 North Broad street, Philadelphia.

Capitol Hill Garage Co., 615 B street, Southeast, Washington, D. C., is now nearing completion.

Cleveland Motor Car Co., of Cleveland, have appointed two new distributors, namely, C. W. Poole, 714 Sixth avenue, Seattle, Wash., and Van Automobile Company, 4706-8-10 Washington avenue, St. Louis, Mo.

Continental Automobile Co., The, of Grand Rapids, Mich., will soon be in their new garage at 93 Jefferson avenue, where they will have a complete, modern and up-to-date salesroom, storage-room and repair shop.

Crown Auto & Cycle Co., 360 Elmwood avenue, Providence, R. I., are now in the market for the agency of some good automobile.

Champaign Automobile Co., of Champaign, Ill., has been incorporated to establish a garage.

Campbell Corwin Company, is erecting a garage at 906-910 Union street, Brooklyn, N. Y. The building for the first two stories will be 75x90 feet. The third story on the rear will be 50x75. The building will be of fireproof construction thruout, and the front will be finisht in buff brick, with limestone and terra cotta trimmings.

Cumbe Co., E. R., has moved into a new garage at 1541-1547 Cleveland Places, Denver, Col.

Dietrich Co., O. H., Ltd., of Allentown, Pa., dealers in automobiles and supplies have been succeeded by the Dietrich Motor Car Co. with the following officers: President, G. J. Heintzleman; secretary and treasurer, O. H. Dietrich.

DuPont Garage Company, 2020 M street, Northwest, Washington, D. C., has recently purchased the Washington branch of the Electric Vehicle Co., of Hartford. The company now has the agency for the Columbia, Rambler and Cleveland lines of cars. They will also continue to operate the old Panorama Building, at 15th and Ohio ave., as a commercial branch.

Davis & Treat have opened a new garage and repair shop at 3 Church street, Adrian, Mich.

Doll, Augustus, has opened a garage at 131 East Philadelphia street, York, Pa., where he will handle the Ford in that vicinity.

D'Archy, Scott & Co., 524 Golden Gate avenue, San Francisco, Cal., agents for the Dragon and Compound cars, have opened a new garage at 611 Valencia street, called the Mission Garage. They have also been appointed agents for the Craig Toledo car.

Delaware Auto Storage & Repair Co., The, of Wilmington, Del., now owned by J. S. Richardson, has greatly improved its facilities. New stock has been installed and the repair department has been enlarged.

Day, Horace B., of San Diego, Cal., has begun the erection of a large garage at 1144 First street.

Darracq Motor Car Company has opened a repair shop at 20 West Sixtieth street, New York City, having decided to use their old quarters at 1989 Broadway solely for show-room purposes.

Evans Motor Car Co., located at 719 First avenue, South Minneapolis, Minn., is building a new garage. 50x125 feet, on Hennepin avenue, between Fifteenth and Sixteenth streets, which they will occupy when completed. The company are agents for Mitchell, Wayne and Jewel cars.

Ellis Motor Car Company, of Newark, N. J., will handle the Knox cars in that city.

Fort Smith Automobile and Supply Co., of Fort Smith, Ark., is erecting a garage on North Twelfth street, near Garrison avenue.

Fargo Auto Brokerage and Garage Company, capitalized at $50,000, will occupy new quarters on Broadway, N. Y.

Fee, Robert L., of Detroit, Mich., will build a garage to be devoted exclusively to use of electric automobiles. The garage will be located on the south side of Jefferson avenue, just east of St. Antoine street, and will be operated under the name of the Fee Vincent Co.

Geisel Automobile Company, of Springfield, Mass., are erecting a one-story concrete garage in Taylor street, which will measure 100x175 ft. and cost about $10,000.

Goodwin Automobile Co., has opened a garage at 612-616 Mulberry street, Des Moines, Ia., and have secured the agency for the Rambler and Mason cars.

Howe W. C., of Camden, Me., has recently opened his new garage and supply room in connection with his repair shop, at Washington and Mechanics street.

Hathorn Auto Co., of Mason City, Ia., has completed an addition to its garage, 40x80 feet in size.

Huntsville Motor Car Co., of Huntsville, Ala., will establish a garage on Gallatin street, that place.

Hutchinson Garage Co., 29 East Avenue A, Hutchinson, Kan., operated by Lou Smith and P. B. Horner, act as agents for the Cadillac car and also carry a full line of accessories.

Harvard Automobile Company has moved into its new garage at Quincy Square, Cambridge, Mass. The building is two stories in height and measures 125x200 feet, affording accommodations for nearly 200 cars.

Henderson, Charles G., Philadelphia, is building a one-story garage at Fifty-first, north of Westmoreland, at the cost of $8000.

Imported Car Repair Co., incorporated under the New York State laws, will install in the Motor Mart of New York, at Broadway and Sixty-second street, a machine shop for the purpose of repairing the highest grades of automobiles.

Inland Auto Co., of Spokane, Wash, is building a new garage.

Illinois Mobile Co., of Chicago, representing the Gearless car, has opened at 1253-55 Michigan avenue.

Koehler, H. J., of 845 Broad street, Newark, N. J. has leased the building at 1709-1711 Broadway, New York City, where he will handle the Buick. In addition to the Broadway he operates garages at Newark, Montclair, East Orange and Paterson, N. J., where he sells the Buick, Corbin and Pope Waverly.

Kaw Valley Auto Company, of Kansas City, Mo., has opened a garage in that place.

Knox Motor Truck Company, of Springfield, Mass., have closed a contract with the Crane Automobile & Garage Co., of Providence, R. I., to represent the Atlas runabout in that section.

Keystone Motor Car Co., 238 North Broad street, Philadelphia, Pa., have started the erection of their new building on Broad street, just south of their present quarters.

Lake Avenue Automobile Co. will erect a garage on Lake avenue, N. W., opposite West Eighty-first street, Cleveland, Ohio. The building will be a one-story brick construction, 38 feet wide and 150 feet deep.

Leonard's Auto Station, H. M., located at 625 West Broad street, Elyria, Ohio, is one of the best equipt and up-to-date garages in the State. The building is 40x167 feet. Mr. Leonard has the agency for the Jackson line of automobiles.

Logan Construction Co., of Chillicothe, Ohio, has established agencies with the following: The Essex Automobile Co., Newark, N. J.; The South Broad Automobile Co., Philadelphia, Pa.; Commercial Auto & Supply Co., Washington, D. C.; F. M. DeRivas, Mexico City, Mexico; Wichita Auto Co., Wichita, Kansas.

Milwaukee Motor Car Supply Company has opened salesrooms at 115 Wisconsin street, Milwaukee, Wis., and will carry a line of automobile supplies.

Martin Bros. have recently opened a garage and repair shop at Akron, N. Y., located on Eckerson avenue.

Morrison, M. M., is erecting a one-story garage at 118 and 122 East Tenth street, Los Angeles, Cal. The building will be of brick, 60x70 feet.

McClure, Mr., of Oskaloosa, Iowa, agent for several makes of cars in that section, is building a garage at Ottumwa, Iowa. The garage will be one-story high, 66x55 feet, of fireproof construction, and will be located at Second and Green streets.

Nickerson Automobile Co., F. A., agents for the Pierce cars, are erecting a two-story garage on Congress street, Portland, Me.

Northampton Garage Co., of Northampton, Mass., will erect a garage at that place. The building will be of brick, two stories high, 40x90 feet.

Nicholaus, Louis, of Schenectady, N. Y., will erect a garage on North College street.

Nussbaum, E. P., formerly manager of the Automobile Supply Department of the National Electric Supply Company, of Washington, D. C., has been elected president of the newly-formed New York Auto Sales Company, doing business at 1968 Broadway, New York City.

Northwestern Automobile Co., of St. Paul, Minn., has opened a branch house at 354 Market street, to be conducted in connection with the main business.

Putnam, F. D., of 827 Elm street, New Haven, Conn., has been appointed agent for the Rainier car, in that section.

Park Garage Co., with a garage at 210 W. Ohio street, Pittsburg, Pa., will introduce the Walter car.

Philadelphia Motor Car Co., of Philadelphia, Pa., with offices in the Land Title Building, and garage at 236 North Broad street, have secured the agency for the Frayer-Miller Car.

Poor & Hooper, of Saco, Me., have opened their new garage on Thornton avenue, and are prepared to do general repair work and store cars.

Philadelphia Auto Sales Co., with W. H. McLain as manager, has opened offices at 332 North Broad street, Philadelphia, Pa., and will represent the Reliance, Jewel and Dolson cars in Southeastern Pennsylvania.

Powell, A. G., 1519 Spring street, Philadelphia, Pa., has acquired the agency for the Chalfont, a 22-25-horse power, $1500 car, built at Lenover, Chester County, Pa.

Rees Company, The, is operating an up-to-date garage and machine shop at 45 West Sixty-second street, New York City.

Roenbeck, Henry, has opened an establishment at 242 Halsey street, Newark, N. J., for vulcanizing and repairing tires.

Rarig Automobile Co., The, 540 Golden Gate avenue, San Francisco, Cal., have recently taken the agency for the Chadwick cars in Northern California.

Roberts & Co., O. G., of Columbus, Ohio, are planning to erect a garage on East Gay street, between Seventeenth street and Miami avenue, that city. The structure is to be of cement blocks, and have a floor space of 72x145 feet.

Sweeney & Neil Auto Co. has organized at Brooklyn, N. Y., and opened an agency at 59-61 Court street, where they represent the Kisselkar.

Spencer, Edgar, of Indianapolis, Ind., has opened a garage on Centre street, and will be styled the Winona Auto & Electric Co.

Tilden & Co. have opened a garage and repair shop at 652 Woodward avenue, Detroit, to succeed Henderson Bros.

Southern Automobile Company, of Asherville, N. C., has taken the agency for the Rambler for Western North Carolina.

Stratton Co., H. C. Boston, agents for the DeLuxe line of cars, will soon move into new salesroom at 173 Huntington avenue.

Syracuse Automobile Supply Co., of Syracuse, N. Y., has opened a garage at 118 South Clinton street, and will sell the Maxwell.

Southern Automobile Co., of Baltimore, Md., has moved its garage and salesroom from Mount Royal garage, Maryland and Mount Royal avenues, to the new headquarters, at 1200 Mount Royal avenue. The company has the agency for the Pierce Arrow.

Standard Automobile Company, of Pittsburg, Pa., will break ground in Aiken avenue for a six-story fireproof garage, 100x150 feet. The structure when finished and equipt with machinery will cost $200,000.

Warner & Co., C. P., Chicago representatives of the Moline, have moved to 1502 Michigan avenue.

Wayne Automobile Company, Detroit, Mich., have established new agencies as follows: Solliday Motor Car Co., 321 Fourth street, Milwaukee, Wis.; Western Auto Co., Denver, Col.; John S. Watters, 233 Baronne street, New Orleans, Louisiana; M. Francis Kane, 507 Mutual Life Building, Seattle, Wash.; J. A. Cramer, 737-741 Main street, Buffalo, N. Y., and Berger Automobile Co., 2025 Farnam street, Omaha, Neb.

Western Automobile Company is erecting a garage at 1928-30 North Twentieth street, Philadelphia, Pa. The building will measure 36x115 feet.

1908 Show at Hartford, Jan. 14 to 18

The Hartford Automobile Dealers' Association met in the Henblein Rathskeller on May 28, and prepared plans for the holding of an automobile show in Foot Guard Hall from January 14 to 18, 1908. The main floor and stage will be used entirely for automobiles. The gallery and basement will be used for exhibits of tires, parts and accessories. The admission price will be 25 cents.

Another Successful Saleswoman

Since the publication of an article in our June, 1907, number, page 229, regarding Miss Brewster, of Philadelphia, selling electric cars for the Foss-Hughes Motor Car Co. we have been informed by the Park Automobile Co., 4432 Olive street, St. Louis, Mo., that Mrs. Gertrude Bradford has been in the business for the past two years in Boston and St. Louis and has driven everything from a sixty-horse-power touring car to a light runabout. She has also been very successful in making sales.

The Thomas Line formerly handled in Philadelphia by the United Motor Car Company, 215 North Broad street, is now handled by Harry S. Houpt, located at 139-141 South Broad street. Mr. Houpt carries the Thomas line in New York city.

Martin-Evans Co., 1186 Bedford avenue, Brooklyn, N. Y., are manufacturers of Tourist inner tubes, and also solid rubber tires for vehicles of every description. They are also exclusive Long Island agents for the products of the Firestone Tire & Rubber Co.

A. F. Justin, who recently resigned as manager of the Penn Auto Supply Co., of Philadelphia, has taken charge of the Providence, R. I., branch of the Angier Co., of Boston. The Angier Co. have completed alterations in the Providence store which doubles its floor space.

A St. Louis dealer has supplied the gipsy king of Kansas with a very unique motor vehicle, which is a combination of the old gypsy wagon and the modern motor car. Such vehicles, only more elaborately equipt, are now being used in Europe by wealthy men who desire a pleasant summer's outing with their families, and yet wish to be independent of hotels.

A. W. Kirk, who has formerly traveled the Southern territory for the Hartford Rubber Works Company, is soon to open a store in Atlanta, Ga., for them and carry a complete stock of Hartford goods at that point. Business thruout the South in the products of his company is booming. The new Hartford Clincher and Dunlop Tires with the Midgley Anti-skid Tread is in great demand in that section.

Commercial Motor Car Department

Experience of Commercial Motor Car Users

Using a Seven-Ton Truck in the Wholesale Grocery Business

J. H. Allen & Co., Allen Square, St. Paul, Minn., manufacturers, importers and wholesale grocers, are at the present time operating one seven-ton truck, manufactured by the Four Wheel Drive Wagon Co., of Milwaukee, Wis. It is rated at 40-horse power, gasoline, capacity seven tons, altho they claim to have carried as high as fourteen tons without difficulty or apparent strain on the machine. It is figured to drive with high speed at eight miles an hour, while they think six would be plenty fast enough for it, and would result in more power for emergencies, and give the opportunity of using high speed and second speed in great many instances where now they are compelled to use the slow speed and intermediate.

Their receiving department's load report for May 11th was 66,000 pounds; May 10th, 67,000 pounds; May 9th, 45,000 pounds; May 8th, 63,300 pounds, making an average of from 30 to 35 tons per day. They use about ten gallons of gasoline per day, lubricating oil and grease about 25 cents' worth per day. In the summer time they run a little lower on gasoline than in the winter time, so that ten gallons is a liberal figure.

They estimate that the machine takes the place of three and one-half heavy trucks.

Their draying, outside of what is done by the truck, has always been by contract on a tonnage basis, and as long as the truck will pull 30 tons per day they have no complaint to make about its working capacity. The most needed improvement in the car as suggested by their experience is a clutch, sufficiently strong to avoid slipping, and a lower gear, so that the machine will develop more power in cases of emergency, altho they confess that even now it is wonderfully strong, and there is seldom an occasion to resort to the winch with which it is equipt in order to extract it from a mud hole. They have their own garage and tool shop in connection and contemplate operating a couple of these cars in the future, keeping one of them in reserve for an emergency car so that in case one should meet with a mishap, the other car can promptly take its place while the one in trouble is being repaired. In this way, they state, it will warrant their keeping one man to look after the cars, and see that they are kept up to the top notch all the time. As they have a competent mechanic to make all of their repairs, this item has been nothing as yet. They claim that if they had to rely on an automobile house to make adjustments they would probably have quite a bill for repairs. So far they have not had any occasion to call in outside assistance since they commenced operating the truck, September 1st last, and since they have received the large axles that are put on all of the later machines, their troubles have practically ceased.

Logan Car Very Satisfactory in Laundry Business

The White Laundry Co., Chillicothe, Ohio, in giving their experience with motor cars, state that their business has increased fully a third since they put on a motor car. They had some trouble at first, but the time gained and the money saved more than offset any troubles they have.

They use a Logan light delivery, Model N, 10-horse power, air-cooled gasoline car built by the Logan Construction Co. The average load carried is 500 pounds and about 30 miles are covered each day in four trips. They cover the entire city of Chillicothe, which has 18,000 inhabitants. The car costs $1000. The average expense per month for gasoline is $7.50 and for lubricating oil $1.60. Repairs are figured at $5.00 per month. The operator's wages are $10 per week. They store their own car. They figure the car depreciates about $200 in value in a year. The car replaces two horses and two light delivery wagons. The wagons cost $100 each and the horses $150 each; harness, $18 per set. Cost and care of each horse was $15 per month; shoeing, $6 per year, and repairs $3 per month. Wages paid for driver were the same as at present. They figure the wagon depreciates in value about one-third in a year and one horse died every four years. Two trips were made per day. They state that the horse-drawn vehicle has no advantages over the motor car, and that the motor car gives quicker service, is less costly and is a great advertiser. The most needed improvement in motor cars as indicated by their experiences is to make them stronger in construction. They also think it advisable for manufacturers to give more explicit information to drivers. They think the Logan car is just right, especially so for laundries.

Hosted by Google

Motor Car in Fire Department has Many Advantages

The chief of the Chicago Fire Department, Chicago, Ill., is using a Buick, Model C, gasoline touring car of 22-H. P. to respond to fire alarms. The car cost them $900. Its average daily mileage is about 50 miles and the radius of territory covered about 25 square miles. Gasoline costs them $6.75 and lubricating oil $2.00 per month. Monthly repairs are figured at $5.00 and tires at $10.00. Average monthly wages of operator and helper are $103.91 each. They figure a car depreciates $50.00 in a year. They claim the motor car can cover more miles in less time than the horse-drawn vehicle, but that the horse-drawn vehicle is less liable to break down.

Before using a motor car they used a horse and buggy, with which they made an average of 10 miles a day. The horse cost $200 and the buggy about $225. Average monthly cost of shoeing amounted to $10.00. Monthly cost of care and feed is figured at $15.00; repairs about $15.00; wages the same as today. They figure that a horse depreciates in value about $25.00, and the buggy $20.00 yearly.

In order to fully meet their requirements they state that cars should be heavy and be made of very best materials to be had. With the motor car they have made a run of 6½ miles in 19 minutes in responding to an alarm, which would have taken a horse about 45 minutes. The most needed improvement in motor cars as suggested by their experience is that they should all have standard size bolts and threads.

Olds Cars Successful in Bus Line

L. E. Bussey, 287 Meldrum avenue, Detroit, Mich., is using two Olds, Model F, 18-H. P., commercial cars for carrying passengers. He runs one car on a 6-mile trip at 25 cents per passenger, and one car on a 19-mile trip at $1.00 per passenger. The routes are over fair asphalt pavements and good macadam roads. The net profit on these two cars last season, June to September inclusive, was $3200.

The average weight of load, 20 passengers, is about 3000 pounds; the daily mileage, 50. The cars cost $3000 each. Average monthly cost of gasoline is $29.40, at 14 cents a gallon—30 days running—and lubricating oil, $3.74. Repairs, including tire replacement, are figured at $9.00 per month. He stores both cars at a cost of $15.00 per month. The average monthly wages of operators are $65, and of conductor, $48. He figures the car depreciates in value about $300 a year. He claims the most needed improvements to cars as suggested by his experience are solid tires that will stay on the wheel until worn out, and more accessibility to motors, etc. Mr. Bussey is using 34x4¼-inch side wire tires at present. He claims it to be impossible to get more than half the wear that they should give on account of being unable to keep them on the rims. He says everybody has the same trouble no matter what the make of tire. He has used three different makes, two side wire and one clincher, but has no preference, they all acting the same for him. He thinks more attention should be put to spring suspension, whether for freight or passenger service, and more accessible motors are needed for commercial work, so that repairs and adjustments can be taken care of in the least possible time. People in the passenger business especially realize the importance of this on account of keeping up to schedule. Mr. Bussey has had trouble in getting good drivers, claiming that many are competent drivers, but cannot be trusted to look after cars properly. He stores his own cars and hires drivers who can make all ordinary repairs. He states that in his line of business a horse-drawn vehicle wouldn't be "in it" for a minute.

Get There Faster with Automobile

Dr. Joseph Rogers, Donnybrook, N. D., in giving his experience with the automobile in his profession, states that with the automobile he can get around faster, can spend more time in his office, and that the automobile is much cheaper.

He uses an Olds, Model N, 8-H. P. gasoline car, costing $700. Gasoline costs him $10.00 per month, and lubricating oil $2.00. Repairs are figured at $5.00. He stores his own car. Dr. Rogers covers about 25 miles a day, two trips, two to four calls per trip. He figures the car depreciates $100 first year, $50 a year thereafter.

Prior to using the motor car, Dr. Rogers employed two horses and one carriage. The horses cost him $165 each, and $35.00 for each set of harness. His carriage cost $85. The average monthly cost of care and feed of each horse amounted to $15.00. Average monthly cost of shoeing each horse, and repairs to vehicle was $2.00 each. He figures the horse and carriage depreciate each $25.00 a year.

As a needed improvement to motor cars, Dr. Rogers suggests more clearance, also better means of supplying electricity for the spark. In order to fully meet the requirements of his profession, Dr. Rogers states that the motor car body and engine should be made of best material; cushion tires; more clearance; good carburettor; good, large gasolene tank, good oiler and transmission, and an extra drive chain should be carried if car is chain driven.

Fred. W. Wolf, Jr., Chicago, Ill., is conducting an agency for Gaeth light and medium size delivery wagons, and is also selling the Wanderlust 2000-pound wagon, his own manufacture. To complete his line he wishes to add a truck, and will be glad to hear from manufacturers.

removing the shaft sections. The radia-
n is accomplished by the use of a front
liator and a series of tubing hung under-
ath of the top frame in the rear of the en-
e. No fan is used.

Olympia Commercial Show

The first motor exhibition at Olympia, ndon, confined solely to commercial ve-les and motor boats, proved a complete cess. There were 230 exhibitors, of ich 80 stands were occupied by commer-l vehicles. On the majority of commer-l vehicle stands motor omnibuses were ged, giving witness to the relative im-tance of this branch of the industry at present time.

The Gibson Automobile Co., Indianapolis, ., is preparing to enter the commercial icle business on a large scale. The com-y is building a fireproof garage on Mas-husetts avenue, almost doubling the size the plant, and will be used exclusively trucks and delivery wagons.

An automobile service, known as the "Auto xe," will soon be introduced in New York. "Auto Luxe" was started in Paris some nths ago, and its purpose is to rent to the lic specially-built and handsomely-finished n cars with experienced drivers in liver- These cars may be hired by the week, night or month.

The American Silk Dyeing & Finishing , Hawthorne, N. J., testify that they are y well pleased with the results obtained m the motor car over those of the horse-wn vehicle, both for better service and aper rates. They have their hauling e by motor vehicles owned by a truck-company, and figure that they save ut 10 per cent. over and above what they nerly paid the railroad company.

automobile stage line will be established between and Fort Collins, Colorado.

passenger service between Rawal Pi and Murree. The route is of an especi ly severe character, being a constant s cession of sharp grades up and down. Pr to the placing of the order for th buses, a series of competitive tests w held, and the White cars showed up well that they were selected for the wo despite the local prejudice in favor English-made articles.

ded the horse and the proverbially slow l uncomfortable local train for the more asant, rapid and in this case cheaper thod of travel, the automobile.

Mr. E. E. White, 2814 North ave., Balore, Md., wholesale salesman of notions l white goods for Carter, Webster & mpany, of that city, has been using a ck 24-H. P. runabout since last Octo- for transporting himself and goods over extensive territory embracing York Coun- Pa., Maryland and part of Delaware. used the machine until Christmas, then l it up until March, since which he has d it continuously five days a week for iness and on Sundays for pleasure, and tes that he has not had any trouble with Furthermore he estimates that by using machine he can save from $400 to $450 year and increase his sales $8000 to ,000 a year. He uses the car on all kinds roads and some very bad hills, but says has never refused to go up any of them . The deck was removed and a large ly, held by four bolts, made to take its ce, and on this about 600 pounds of nples and baggage are carried. The deck be easily replaced when desired, as it held by only two bolts.

COVERS MORE TERRITORY.

This runabout took the place of a two- rse Dayton rig, with which 25 miles in a , making five to eight calls, was the limit, ile with the auto distances of 40 miles a are easy and ten to fifteen calls can be de. The only time when horses are bet- than the auto are during the spring ws, and even then he believes all that uld be necessary is to have larger wheels.

ADVANTAGES OF AUTO.

The machine, he states, has proved a good vertisement for him, as he attributes the was the case when using horses, and some cases it was necessary to hurry up cu tomers in order to catch a train, and, p haps, injure the amount of the sale. times trains were missed and much ti lost or a team hired at considerable exper in order to reach the next town.

EXPENSES.

The average monthly cost of gasoline $11, and for lubricating oil, $3. The to amount spent in repairs during seven mont use was only $11.50.

Mr. White considers that the deprec tion in the value of a car depends so larg on the care it receives that he cannot put into figures, but says that his machine apparently as good to-day as when n and that he is still using the original of tires. In his own words: "Any c can use a car for years if they just give a little attention and it does not require much as a horse. One can figure on usi an auto on country roads eight to n months a year and I would never think going back to hiring teams again."

Chicago Commercial Vehicle Show Next Fall

At the May meeting of the execut committee of the National Association Automobile Manufacturers, held in N York, it was decided to hold an exclus commercial vehicle show in Chicago n fall. It will be held the same time as pleasure vehicle show, November 30 to D cember 7 next. Altho the shows will held simultaneously, they will be in separ buildings, some distance apart. The ple ure cars will be exhibited in the Colise and the commercial vehicles will be sho in the Seventh Regiment Armory.

FOR TRANSPORTATION LINES, PLEASURE RESORTS, HOTEL WORK, ETC.

Practically the only successful gasoline busses in operation are those which we have manufactured. We make them to carry from 10 to 30 passengers. As an evidence of their practicability, both from a service and profit-making standpoint, we draw your attention to the 30 cars which have been operated the last year between New York City and Coney Island. These busses have carried over 300,000 passengers at the rate of $1.00 a head. **Sometimes each one of these busses have made five round trips a day, a total of over 200 miles.** With the exception of tires, the cars are practically in as good condition to-day as when they went into service.

Our passenger coaches have been in use for five years in all parts of the country, also Cuba and Mexico, and are paying large dividends to the companies operating them. **MANHATTAN BUSSES** are not an experiment but an assured fact, and have demonstrated their reliability in actual service. They are sure profit makers. Capacity 10 to 30 passengers. Bodies in different styles. Upholstering in Cane Seats or Leather.

Motor Cycle Department

Trophy for Motorcycle Competition

R. G. Betts, president of the Federation of American Motorcyclists, will present for team competition between motorcycle clubs, a solid silver trophy. The trophy will cost approximately $150, and will take the form of a shield bearing raised motorcycle designs and laurel wreaths, within which to inscribe the names of the successive victors. The trophy will be styled the Betts shield, and the donor has stipulated that the first contest shall occur at the national meet of the F. A. M., held at Providence in August.

F. A. M. Endurance Run

After several changes, the dates for the national meet of the Federation of American Motorcyclists at Providence, R. I., have been finally changed to August 1, 2, 3 and 4. This results in the starting of the F. A. M. endurance contest from New York at 4.30 A. M. Tuesday, July 30. The first day's run will be to Springfield, Mass., 190 miles, via Poughkeepsie, N. Y., Lakeville, Conn., and Lenox, Mass. The following half day the route will be from Springfield to Providence, via Worcester, 87 miles. Poughkeepsie, Springfield, Worcester and Providence will be the controls at which the contestants will be timed.

The schedule will be worked out on a basis of 15 miles per hour, the penalties to be one point for each minute the rider is late and two points for each minute he may exceed the schedule, five minutes leeway, fast and slow, being allowed for variation of watches; no competitor, however, will be permitted to come within sight of a control and there wait for his time to expire. Repairs within controls will be prohibited.

The contestants will be divided into two classes, A and B, the former being constituted of those riders using single cylinder motorcycles, and the latter of those using two or more cylinders.

Each starter will be given an initial credit of 1000 points. In addition to trying the rider's endurance and judgment of pace, the hill-climbing qualities of his mount and the economy of its operation will be put to test. The climbing qualities will be tried out on the westerly slope of Jacob's Ladder near Lee, Mass.

The test of economy will take place on the Hills Grove half mile track in Providence, immediately on the arrival of the indurancers.

The first ten men in Class A and the first five in Class B will be designated "Honor Men"; the leader in each class will be awarded a diamond medal, while the other "Honor Men" will receive combined gold and silver medals, the number of awards in the multicylinder class being contingent on there being not less than 12 starters. There also will be awarded to the private owner unconnected with the trade, and regardless of his class or position in the general score, a special gold medal, but he must have owned his machine at least 15 days previous to the start of the contest; this gold medal will be awarded in lieu of any other to which his standing may entitle him, the diamond prize only excepted.

The entry fee will be $5 and the list will close July 20, with H. J. Wehman, chairman, 108 Park Row, New York.

Providence Chooses Three Championships

The Providence Motorcycle Club has chosen three national championship events for leading events at the annual meeting of the F. A. M., at Providence, R. I., August 1 and 2. These events will be the one, two and ten-mile distances. This leaves the five-mile and the one-hour championships still open for decision.

Wray Establishes Motorcycle Record at Wilkes-Barre

A record of 1 minute 40 seconds was established at Wilkes-Barre on Memorial Day by William H. Wray with a 14 H. P. Simplex motorcycle. Besides establishing a record Wray won the free-for-all event, in which there were five starters. The record is considered a wonderful performance, as the climb of 6909 feet was made at an average of 40.9 miles per hour. The summary:

1 W. H. Wray, 14 H. P. Simplex...1.40
2 J. E. McLaughlin, 4 H. P. Indian..2.18
3 G. W. Sherman, 4 H. P. Indian....2.24 4-5
4 C. T. Anderson, 1¾ H. P. Indian..2.48
5 Oscar Hedstrom, 12 H. P. Indian..2.54

Harley-Davidson Carries off Honors in West

The Harley-Davidson motorcycle carried off all the honors at the motorcycle hill climb at Curtiss Hill, Milwaukee, Wis., on Decoration Day. The slow test held only saw two actual finishers, C. H. Lang on his two-speed Harley-Davidson and R. D. Buell on his two-cylinder Rex. Summary follows:

R. Sporleder, Mil'kee, Harley-Davidson..	.42	.41 2-5
W. Davidson, Mil'kee, Harley-Davidson.	.43 1-5	.42 1-5
F. Huyck, Chicago, Harley-Davidson...	.43 1-5	.42 1-5
R. D. Buel, Chicago, Two-cylinder Rex.	.44	.43 1-5
J. G. Turner, Chicago Special Armac...	.49 1-5	.45
C. Blankenheim, Chicago, Torpedo.....	.47	.46 1-5
G. W. Lyons, Chicago, Antoine-Torpedo.	.46 2-5	.48 3-5
C. Newbauer, Milwaukee, Merkel.....	.49 2-5	.52 4.5

Fulton County Motorcycle Association Races at Johnstown

On Memorial Day at the Johnstown (Pa.), Fair Grounds the Fulton County Motorcycle Association held their first annual field day. There were six events in all, four for motorcycles and two for bicycles. About seven hundred persons attended the races.

Summaries:

One mile motorcycle race for novices, won by F. S. Smith, Johnstown, riding an "R. S.," time 1:47 3-5; second, J. Shear, Gloverville, Indian; third, J. R. Vosburgh, Johnstown, "R. S."

Five mile county championship, F. S. Smith, "R. S.," 8:46; second, J. R. Vosburgh, "R. S.;" third, J. W. Sisson, Indian.

One mile bicycle, novice, R. Gross, Gloverville, first.

One mile county championship (bicycle), D. Quackenbush, first. Time 2:53.

Unlimited pursuit race between teams from Johnstown to Gloversville. Riders made 27 miles in forty-six minutes and fifty-five seconds, an average of 1 minute and 44 seconds per mile. The contest was decided a tie between Vosburgh and Sisson.

Five mile for motorcycle belt-driven machines, L. Bremer, Gloverville, M. & M. Time 13 minutes.

Motorcycles Climb Manhasset Hill

On May 30th the fifth annual hill climbing contest of the New York Motorcycle Club in conjunction with the Brooklyn Motorcycle Club, was held on Manhasset Hill, Brooklyn.

In the first event, Class 1, Stanley T. Kellog, of Springfield, Mass., defeated Percy J. Drummond, of Newark, N. J., by three-fifths of a second. Both rode Indian machines. Results:

Class 1—Stanley T. Kellog, riding Indian. Time—1.14 4-5.

Class 2—Albert Book, riding Curtiss. Time—1.04 1-5.

Class 3—G. H. Curtiss, riding Curtiss. Time—0.50.

Class 4—G. H. Curtiss, riding Curtiss. Time—0.56 2-5.

F. A. M. Work

One of the good works in which the F. A. M. is engaged is the organization and designation of a system of accredited and competent repair shops, which work already has made substantial progress. Shops owned by such dealers and repairmen as pass the examination, which requires that certain stock and equipment be carried and that the applicants themselves shall be motorcyclists of at least two years' experience or have a rider of such experience in their employ—are officially registered, and a handsome gold bordered certificate issued (without cost) setting forth the fact. On the "Selected Routes," which the F. A. M. is issuing to its members, the names and addresses of all such accredited repairers are being printed without charge.

The first of the series of "Selected Routes for Motorcyclists," to be issued by the Federation of American Motorcyclists, is almost ready for distribution. It covers the route from New York to Providence and Boston via the Berkshire Hills and return via the Hartford-New Haven route and is laid out in a manner that permits the choice of either a day's run or a week's tour, the idea of the series being to present circular or "unrepeated" routes. The routes will be issued separately on waterproof cloth and will be of a size that may be carried in the pocket, and when the series is completed be made into a built-up book with detachable pages.

Motorcycle Show in November

As a result of the influences brought to bear on the Association of Licensed Automobile Manufacturers by the Cycle Manufacturers' Association the licensed association has let down their bars and will allow motorcycles to be exhibited at the Madison Square Garden show in November.

C. E. Bradley Motor Co., of Philadelphia, manufacturer of motors and motorcycles, have set up a department for the repair of foreign motorcycles.

The Reading Standard Co., Reading, Pa., has found it necessary to increase its manufacturing facilities in order to keep pace with the demand for Reading pedal cycles and R-S motor cycles, and has therefore purchased the business and plant of the Reading Machine Co.

The Milwaukee Motorcycle Club has elected the following officers for 1907: Dr. Thomas, president; J. T. Ball, vice-president; Arthur Davidson, secretary; Arthur Morgan, treasurer. Directors: Ralph Sporleder, Arthur Kellerman, Herbert Taylor, Dr. Thomas and Arthur Davidson.

At a meeting on June 5 the Pikes Peak Motorcycle Club was organized with a charter membership of thirty. The club was organized to promote motor cycling and for the benefit of the riders no dealer being allowed to hold office.

The following officers were elected: President, H. Holman; vice-president, N. S. Norton; secretary, Chas. B. Lansing; treasurer, Alva Stratton.

The C. M. A. annual election resulted as follows: Fred I. Johnson, president; vice-president, Ignace Schwinn, Arnold, Schwinn & Co.; secretary, J. F Cox, Pope Mfg. Co.; treasurer, Harry Walburg, Reading Standard Co. Messrs. Cox and Walburg succeeded themselves. The report of the Cycle Show Committee reporting that unexpected advancement of the dates of the New York automobile show had upset or wholly altered the situation respecting the proposed exhibit of cycles and motor cycles, and recommending that the latter be deferred until 1909, was received and adopted.

v "Simplex" Motor Cycle Accessories

he Prospect Motor Mfg. Co., 7 and 9 k Place, Brooklyn, N. Y., are offering e new products to the trade, consisting lamp and generator, a siren horn and ble clip.

a large reflector in the rear, and is identic in appearance with the regular automobi type lamp. Price is $10.00.

The "Simplex" Cable Clips.

Their Simplex siren horn is made aluminum, runs on ball bearings and is a tached to the motorcycle by means of strong clamp. It is operated by a Bowde wire, which brings the small wheel in co tact with the front tire. This horn, th claim, can be heard ½-mile. Its list pri is $16.00.

The Simplex cable clips are made aluminum. They are intended to elimina all trouble from short circuit, and to ho all the wires very snugly in the frame. Th do away with the necessity of using ti tape, etc. These clips sell for 50 cents dozen or $2.50 per 100.

A. J. McCullom, the motor Racycle exper who left the factory at Middletown, Ohi on April 3, arrived in Boston, the end his journey, on May 29, having covered 19 miles.

The ten miles to the summit of Mt. Wi son, the site of the Lick Observatory, wa covered by Edward Loudenclos, a young mo torcyclist of Pasadena, Cal., in the recor breaking time of forty-nine minutes, ar returning made the descent in forty-fiv minutes. Loudenclos is secretary of the Pa adena Motorcycle Club and rides a Readir Standard motorcycle.

Campbell to Manage National Motor Boat Shows

Chester I. Campbell, 5 Park Square, Boston, has been appointed by the National Association of Engine and Boat Manufacturers, New England Engine and Boat Manufacturers and American Association of Engine and Boat Manufacturers to have full charge of the three motor boat shows to be held under the auspices of these three associations as follows:

The New York Show at the Grand Central Palace, from Dec. 7th to 14th, 1907.

The Chicago Show to be held at such exhibition hall and time as he may decide upon.

Boston Show to be held in Mechanics' Hall January 27th to February 1st, 1908.

The associations named above sanction only the shows in the schedule named. They have further authorized him to solicit exhibition space among the members of the respective associations and manufacturers in the trade for these shows with power to make contracts and arrange all details for such exhibitions.

The members of the National Association of Engine and Boat Manufacturers have recently received a statement from the treasurer, showing the present excellent financial condition, a balance showing nearly sixteen thousand dollars in assets, and no indebtedness. A division of a portion of this sum was contemplated, but on further consideration the Executive Committee determined that it would be better to utilize the fund as a guarantee for the coming New York Boat Show, and to help support the shows which will be held in Boston and Chicago under the auspices of the New England Engine and Boat Association and American Association of Engine and Boat Manufacturers.

It is the wish of the Executive Committee to so arrange with members who exhibit that they may participate in the net return from these shows, thereby to reduce the ultimate cost of space to a minimum, if not in its entirety.

A. P. B. A. Cruise to Jamestown

The 1907 cruise of the American Power Boat Association will be to Jamestown Exposition, the start to be made at 1.30 P. M. on August 23, from the Atlantic Yacht Club, Sea Gate. The first day's run will be to New Brunswick, N. J., where the night will be spent in the basin of the Delaware and Raritan Canal. On August 23 the run will be to Riverton, N. J., and August 24, to the entrance of Chesapeake and Delaware Canal, at Delaware City, Del.; August 25, short run on Delaware canal, and south to Sassafras river; on August 26, to Annapolis, Md.; on August 27, to Soloman's Island, Va.; on August 28, to Milford Haven, Va., and on the night of August 29 the fleet should reach Hampton Roads Yacht Club.

Arrangements have been made for supplies and gasoline thruout the cruise. Entries are requested as early in the season as possible, in order to facilitate the many arrangements necessary.

Newark Motor and Yacht Club

Newark Motor and Yacht Club, of Newark, N. J., which has only been organized for several months and which has a membership of ninety, opened the season on Decoration Day with a motor boat parade. The start was made from Kroll's boat house at the foot of Chester avenue, with a goodly number of boats in line, gaily decorated with the national and the club emblems. The course was to Bayonne, where a shore dinner was served.

Motor Boat Season Open

The Ventnor Motor Boat Club, of Atlantic City, N. J., which was organized a few weeks ago, opened the season with a parade and races on Memorial Day. The races were over a five-mile inside course. Their first event was won by L. Bye, the second by D. Albertson, the third by A. L. Thome and the fourth by N. Knauer.

Hosted by Google

divided into two classes: for boats 25 and over and boats under 25 feet. Pre- s to the race all boats entered were re- ed by the committee to cover a short se and report their time. On this basis as estimated how long the boats should n covering the race courses of approx- ely eleven miles for the large class and n miles for the small class. The boats ring the courses in the times nearest ap- ching the committee's estimate were de- d winners.

the class for boats over 25 feet Mildred, uxiliary sloop, was declared winner. Her was 1.26.05. In the small class Omo her time over the course being 1.04.30.

e "Sturgeon Bay" Family Launch

order to meet the demand for a good, nch, comfortable family launch, selling price that is within reach of nearly y one, the Sturgeon Motor Boat Mfg.

The "Sturgeon Bay" 23-Foot Family Launch.

of Sturgeon Bay, Wis., offer the 23- family launch shown in the accompany- cut.

e boat is built very heavy, the keel, e work, covering boards, decks, coam- etc., being of white oak, and of ample

been tested out on the rough waters o Lake Michigan and has proved very sea worthy, and a great number of them hav been sold to the smaller lakes, where good, dry, safe and comfortable boat needed.

The concern have under way at present boat with which they expect to make 2 miles an hour.

Ailsa Craig Wins Bermuda Race

The motor boat Ailsa Craig won the rac from New York to Bermuda, crossing th finishing line at 9.59 o'clock Tuesday morn ing, June 11, having covered the 670 nauti cal miles in 65 hours 49 minutes. The boa made good weather of the seas and onl once during the voyage were the engine stopt, which was made in order to shi an igniter.

Thomas Fleming Day who was in charg was loud in his praise of the yacht's per formance. She ran 190 miles up to noo on Sunday, 276 miles up to noon on Mon day and 204 miles to the finishing line. O the trip 550 gallons of gasoline were use Summary:

Start, 4.10 o'clock P. M., June 8. Finish, June 11:

Yacht and Owner.	Finish.	Elapsed Time. D.H.M
Ailsa Craig, Craig & Stevens	9.59 A. M.	2.17.4
Idaho, Peter Shields	7.12 P. M.	3.03.0

Corrected time: Ailsa Craig, 2 days 17 hours 49 mi utes; Idaho, 2 days 18 hours 6 minutes. The Ails Craig wins by 17 minutes.

The engine of the motor boat Ailsa Craig winner of the Bermuda race, was equip with Pedersen lubricators.

Answers to Marine Motor Inquiries

REBORING CYLINDER.

5824 Rural Street.

Pittsburg, Pa., March 20, 1907.

ease give me a little advice in regard to fixing
an engine. I have a 4-cylinder 4-cycle marine
or, 6-inch bore by 7-inch stroke; valve ports
inches diameter, inlet piping 1½-inch, ex-
sts 1½-inch increased to 2-inch. All valves in
head, inlets automatic, compression space 3½
es long. It turns a 28-inch 3-bladed pro-
er 450 R. P. M. I have been thinking of re-
ng the cylinder, to take out scored places,
ing new heads and fitting the valves in cages
nake them easier to take out.

n I increase the power and speed of this en-

GAS ENGINE BUSINESS
FOR SALE

WE offer for sale the drawings, designs, patterns and special tools, such as jigs, templets, etc.; also the good will of one of the best known, extensively advertised, and successful two-cycle marine engine businesses in the country.

This also includes a quantity of finished and unfinished parts, and is an exceptional opportunity to obtain a fully developed line of marine gas engines, and an established business.

For particulars and full information, address,

TWO CYCLE,

Care of Cycle and Automobile Trade Journal.

Ralaco "THE SIMPLIFIED ENGINE"

Just a glance at the accompanying illustration will convinc one at all familiar with marine engines that the RALACO is si ity itself. It has less moving parts than any other make, a adjustments and working parts are more accessible.

The inlet and exhaust passages are cast within the cylinder jacket and connect with passages in the upper part of the h thereby eliminating the usual unsightly hot piping connected cylinders as found on all other engines. A CYLINDER MAY B MOVED IN A MOMENT'S TIME WITHOUT MOLESTING ANY O PART.

Valves are set in cages in cylinder head directly over the p there being no overhanging valve boxes. ALL VALVES AND C ARE INTERCHANGEABLE.

The valve gear, providing mechanically opened inlet, co but half the number of parts found on other engines.

Our perfected system of AUTOMATIC LUBRICATION does awa all lubricators, sight feeds and oil tubes.

Practically all of the working parts are enclosed within th and at all times run in a bath of oil.

If you would have the MOST QUIET running engine on the ket, and one with the greatest number of distinctive featur desirable qualities, do not fail at least to investigate the R

ore buying. We will send you catalogue and full information promptly at your request.

Auto Bodies

It's good to see how quickly Mobo removes mud, grease and dirt from an automobile body. It doesn't matter how long the car has gone without cleaning, or how thick the dirt may be—off it comes, easily and quickly if you use

MOBO

Automobile Cleanser

Not only does it remove all the dirt, but does it without marring or scratching the varnished surface, and without dimming the lustre in any way. That's Mobo style.

Mobo is composed of pure vegetable oils, and contains nothing rough to mark the smoothest surface. It is the ideal automobile cleanser.

Prevents the varnish and paint from cracking and blistering. Keeps the car looking new. It's the best sold to-day. Try it once and you'll understand why.

Put up in 3 lb. and 6 lb. cans; also in tubs, half-barrels and barrels. Can be had at the following supply house:

Gordon Auto Supply Co.
215 Eliot Street
Boston, Mass.

and at all good automobile supply stores in all leading cities.

Send for our Mobo booklet —"*How to Clean Well Varnish and Paint on an Automobile*" It's free.

I Will Prove to You

That

SULLIVANOIL

Is The Best Cylinder Oil

ONE GALLON FREE!

I have found, that when a person begins to investigate the oil question, he generally arrives at the conclusion that a thick, heavy oil which has a great deal of "body" or density is the oil of merit.

This isn't true. A dense, heavy oil is slow acting, difficult to feed properly, and even mechanical oilers cannot deliver it in proper quantity at the proper place.

The other extreme—an oil too thin—must be used so freely as to flood the cylinders, and even then the result is unsatisfactory, for it hasn't enough body to lubricate properly.

There is practically as much residue (carbon) from the one as from the other in the regular cylinder lubricating oils on the market.

Now, after years of experimenting, I have discovered an oil of just the proper density which lubricates any internal combustion cylinder perfectly, and leaves no carbon. There is no residue left after combustion. The particular density or "body" of Sullivanoil is one reason why Sullivanoil is pre-eminently the best of all cylinder oils.

Sullivanoil is of but one grade or density, and you do not have to buy three or four grades to experiment with to find the one grade that is best for your motor.

Talk—promises—arguments are all right in their places but—

I will prove to you by actual demonstrations that Sullivanoil is really what I say: "the best cylinder oil for your motor.

I will do it entirely at my expense

ONE GALLON FREE!

I will give you one-gallon can of Sullivanoil free—no delivery charges—no obligation whatever to you—to try on your car.

Simply tell me that you own an automobile and send me the name of your dealer, and I will have him deliver to you one gallon of Sullivanoil free of all charges.

Send for booklet, "How to Test Oil," which gives many facts about oil that you should know.

Write to me personally.

IF COMFORT INTERESTS YOU

INVESTIGATE OUR

Coat and Foot Rails

Foot rails are a necessity in large tonneau cars, to prevent the occupants fro slipping and sliding on the rear seats. A Foot Rail enables the passengers to sit i comfort even on the roughest roads.

Coat rails allow you to carry robes and wraps so that they will be out of the wa of the passengers and will not become mussed or soiled. They are, too, a handsom addition to any car.

If these comfort-bringers are not supplied by your manufacturer, write for printe matter and prices.

17,896	
2,101	Returned by News Co., to July 16, 1907.
15,795	Net total paid.

We print on this page each month an exact statement of the number of copies printed and distributed of the preceding issue of "The Cycle and Automobile Trade Journal."

The bindery count of actual complete copies produced of the July issue was 20,347.

Of these, 21,843 pounds were mailed at pound rates, as shown by post office receipts. Each copy weighs 22 ounces, representing 15,886 copies, and 2520 copies of back numbers and copies returned by news companies are accounted for, in addition to the total for the month.

We will be pleased to verify the above figures at any time to any one interested.

Knox Automobile Co. Assigns

The Knox Automobile Co., Springfield, Mass., has assigned to Alfred N. Mayo for the benefit of all its creditors, the difficulty being caused by attempting to do too much business on too small a capital. The inventory of July 1st shows assets nearly double liabilities, and the business for the past ten months shows an increase of 87½ per cent. over same period last year. Arrangements for additional capital are being made, which are expected to be consummated in ample time for 1908 business.

Coming Events

July 31-August 8—Belgium Regularity Contest for Touring Cars. A. C., of Belgium.

August 1—Hill climb, Algonquin Hill, Chicago Motor Club and Chicago Auto Trade Association.

Aug. 1-4—Providence, R. I., Federation of American Motor Cyclists, National Meet.

Aug. 1-7—Criterium of France, 1750 miles touring competition and 250 mile race for the press cup. A. C., of France.

August 5-10—Automobile Carnival (Races and Show), Atlantic City, N. J.

August 6—Orphans' Day, under direction of Rochester Automobile Club.

August 8—International Reliability Contest, Belgium.

August 9-10—New York City Brighton Beach Track, 25-hour automobile race, U. S. Motor Racing Association.

August 11-20—Auvergne Cup Competition, France.

August 17—Race Meet Olympia (Wash.), Horse and Automobile Association.

September 1—Italy, Brescia Circuit, Florio Cup, A. C., of Italy.

September 2—Overland Park Track Meet, Denver, Colorado.

September 2—Labor Day Hill Climb, Sport Hill, Bridgeport (Conn.), Automobile Club.

September 4—Padova Bovolenta, Automobile Club of Venice.

September 5—Cedar Lake Economy Run, Chicago Motor Club and Chicago Auto Trade Association.

September 9—Commercial Vehicle Trials of English Royal, A. C.

September 14—95-mile road race, Albany Automobile Club of Albany, N. Y.

September 14-15—Mont Ventoux Hill Climb.

September 15—Semmering Hill Climb.

September 28-October 7—International Automobile Show, Copenhagen, Denmark.

October 1-15—Contest of Electric Vehicles, Automobile Club, of France.

October 6—Cup of L'Auto Maisons-Laffitte.

October 13—Kilometer Contest at Dourdan, under auspices of L'Auto.

October 20—Gallion Hill Climb.

October 21—St. Louis (Mo.), International Aerial Race for the Gordon-Bennett Prize.

October 24-31—Eighth Annual Automobile Show; A. C. A., Grand Central Palace, New York.

October 31-November 7—A. L. A. M. Show, Madison Square Garden, N. Y.

November 11-23—Olympia Motor Show, London.

November 12-December 1—Paris Show, Grand Palais and Place Des Invalides, A. C., of F

November 30-December 7—Chicago National Automobile Show, S. A. Miles, Mgr., No. 7 E. 42d st., N. Y. City.

December 14-21—Local Show, St. Louis, Mo., Auto Manufacturers' and Dealers' Association.

December 28-January 4—Importers' Salon, Madison Square Garden, New York City, C. R. Mabley, Sec. and Mgr.

That the Board of Trade of Trenton, N. J., is keenly alive to the fact that there will result great advantage to the people along the line of the Vanderbilt Race Course, is shown by the fact that they have unanimously past a resolution urging the legislature and governor to pass a bill permitting roads in Mercer county to be used for the race and elimination trials.

Hosted by Google

Fifty-Five Perfect Scores in Chicago Club's Run

On June 28 the Chicago Motor Club held a combined sealed-bonnet and reliability test over a course which included Chicago, Waukegan and Elgin. Of the eighty-six starters fifty-five, representing thirty-one different makes, came thru with perfect scores.

Unlike the sealed bonnet contest of the A. C. A. in New York, the breaking of a seal penalized the violator 50 points with an additional 25 for breaking the seal of the coil box, while in the A. C. A. contest the breaking of a seal eliminated the car.

The total distance traversed was 175 miles for large cars and 148 for small cars.

Tire trouble was the chief obstacle that beset the contestants. The Pierce and the Haynes teams of four cars each finished with perfect scores and tied for the team trophy.

The honors were well distributed, the Pierce getting four perfect scores. The Jackson had six cars and drew five certificates. The Maxwell had in seven, and six of these were perfect. The Ford had five, and three got thru. The Haynes checked thru four, and the Premier landed twice out of three chances. The Locomobile and Columbia each got two, the latter only having that many cars in. The Moline put both its cars thru. Three Buicks are on the roll of honor, which also shows the Dragon, Matheson, Studebaker, Waynes, Oldsmobile, Holsman, Royal Tourist, Pierce Racine, Corbin, Frayer-Miller, Rambler, National, Triumph, Packard, Simplex, Diamond T., Queen, Lambert, Craig-Toledo, Pope-Hartford, Carter Car and Mason.

Two-Day Meet at St. Paul, Minn.

The two-day meet held at St. Paul, June 28-29, ended with a 24-hour race, which was won by Mongini, driving a Locomobile, with a total mileage of 1,037. The meet was managed by the United States Motor Racing Association. Preceding the start of the 24-hour race was a parade of decorated cars, in which about 300 cars participated. A few sprint races were run each day.

FIRST DAY.

Ten miles, for Twin Cities championship—Won by E. C. Bald, Oldsmobile; second, Ed Zerbies, Mitchell. Time, 13.05.

Three miles, for fully equipt runabouts—Won by Dr. D. C. Cowles, Mitchell; second, Charles Ross, Ford. Time, 4.39.

Twenty-five miles for stock cars—Won by E. C. Bald, Oldsmobile; second, Simpson, National; third, Winston, Oldsmobile. Time, 30.58.

Three miles free-for-all—Won by Ralph C. Bagley, Packard; second, Simpson, National; third, Winston, Columbia. Time, 2.38.

Five mile match—Won by R. C. Bagley, Packard; second, Simpson, National. Time, 6.16 4-5.

One mile against time—By George Hilgers, Stanley. Time, 1.05.

SECOND DAY.

One mile against time—Geo. Hilgers, Stanley. Time, 1.04.

Five mile International Sweepstakes for purse of $2500—Won by E. C. Bald, Oldsmobile; second, Ralph Mongini, Packard. Time, 6.07 2-5.

The Motor and Accessories Manufacturers will hold their mid-summer meeting at Atlantic City, N. J., August 8th and 9th.

The Motor and Accessories Manufacturers refused to sanction the projected automobile show scheduled to be held on Young's New Million-Dollar Pier August 7th, 8th and 9th.

Thru Mud and Rain

At a few minutes after 5 o'clock, June 29, the 24-hour race of the Quaker City Motor Club came to a close with the Lozier car as winner.

The run was started June 28 at 5.18 with ten starters, representing eight different makes. The winning Lozier car driven by Harry Minchenor covered 717 miles, driving in a drenching rain nearly all day and with the track in bad condition.

Summary of 24-hour race:

	Miles.
Lozier, Harry Minchenor	717
Frayer Miller, Frank Lawwell	711
Darracq, William Wallace	683
Cleveland, M. La Roche	564
Frayer-Miller, Daniel Webster	499

On Friday preceding the 24-hour grind several interesting sprint races were run. Guy Vaughn with Sterns proved the star of the afternoon with three firsts.

Summary:

Five miles, for city championship, for cars costing $3000 and less—Won by T. W. Berger, Olds; second, Howard Miller, Pope-Hartford; third, George Parker, Olds. Time, 5.50 2-5.

Five-mile open—Won by Guy Vaughn, Stearns; second, T. W. Berger, Olds; third, Howard Miller, Pope-Hartford. Time, 5.44 1-5.

Ten miles, for city championship—Won by Guy Vaughn, Stearns; second, T. W. Berger, Olds. Time, 11.20.

Five-mile Quaker City Motor Club championship—Won by F. Shelton, Stoddard-Dayton. Time, 6.52 1-5. Mercedes did not finish.

Ten-mile open—Won by Guy Vaughn, Stearns; second, T. W. Berger, Olds; third, Howard Miller, Pope-Hartford. Time, 11.14 1-5.

Reading Auto Races

The Berkshire Automobile Racing Association held a very successful tournament July 4 at Shillington track. The winners were:

Two miles—$3000 and under—Walter Lovatt, Haynes. Time, 3:00.

Two miles—$5000 and under—Robert Morton, Pullman. Time, 3:07.

Two miles—$1200 and $2500—Zimmerman, Jackson. Time, 3:05 1-5.

Two miles—Under $1500—Wayne Yerger, Buick. Time, 3:25 2-5.

One mile against time—Paul Messner, Stanley. Time, 2:55 4-5.

Three mile handicap, championship Berks county—Winner Charles W. Krick, Oldsmobile (70 yards); second, Dr. J. M. Bertolet. Time, 4:41.

Two miles—$800 and $1500—M. Kinports, Ford. Time, 3:17.

Five miles free-for-all—Robert Morton, Pullman. Time, 3:00.

Unlimited pursuit—$1200 to $1850—Winner Robert Morton, Pullman; second, Zimmerman, Jackson. Distance, 28½ miles.

M. J. Budlong has resigned the presidency of the Electric Vehicle Co. and Hiram Percy Maxim and Geo. H. Strout have resigned their positions as chief engineer and sales-manager respectively of the same company.

At the meeting of the Board of Directors of the New York State Automobile Association, June 29, the following clubs were added to the roster: Long Island Automobile Club, Adirondack Automobile Club, of Sandy Hill; Automobile Club of Schenectady and Cohoes Automobile Club.

Ninety-Day Guarantee

Following the last meeting, June 27, of the Committee of Management of the American Motor Car Manufacturers' Association, the following bulletin containing the recommended guarantee was sent to the members of the association:

THE STANDARD WARRANTY.

We warrant the motor vehicles manufactured by us for ninety days after the date of shipment, this warranty being limited to the furnishing by our factory of such parts of the motor vehicle as shall, under normal use and service, appear to us to have been defective in material or workmanship.

This warranty is limited to the shipment to the purchaser, without charge, except for transportation, of the part or parts intended to replace the part or parts claimed to have been defective, and which, upon their return to us at our factory for inspection, we shall have determined were defective, and provided the transportation charges for the parts so returned have been prepaid.

We make no warranty whatever in respect of tires, rims and batteries.

The condition of this warranty, is such that if the motor vehicle to which it applies is altered, or repaired, outside of our factory, our liability under this warranty shall cease.

The purchaser understands and agrees that no warranty of the motor vehicle is made, or authorized to be made, by this company, other than that herein above set forth.

More Floor Space Secured for the October Grand Central Palace Show

The Exhibition Committee of the Eighth Annual Automobile Show, to be held in the Grand Central Palace, New York city, October 24 to 31, 1907, under the auspices of the Automobile Club of America, announces that 10,000 square feet more space for exhibition purposes than was available last year have been secured, which will enable exhibitors to make a better showing than heretofore. An interesting balloon exhibit will be made by the Aero Club of America, as in previous years.

The A. C. A. will divide with the exhibitors the net profits of the show, and sent out as early as July 15 floor diagrams and complete information for those desiring to exhibit.

House Passes Race Bill

Trenton, N. J., July 5, the assembly past the bill legalizing the Vanderbilt automobile cup race in New Jersey by a vote of 31 to 5. The bill is now up to the senate.

Importers' Show Dates Set

December 28, January 4, is the date set for the forthcoming importers' show in Madison Square Garden, New York.

Independent Show Dates Selected

As announced by the Automobile Club of America, the date set for the eighth annual automobile show to be held in Grand Central Palace, is October 24 to October 31. Special arrangements have been made with the Grand Central Palace whereby more space will be obtained. The committee has also a new scheme of decorations which is being outlined and which will be announced when the space application blanks and other literature are issued.

16 Events Scheduled for Atlantic City's Carnival

The Contest Committee of the Atlantic City Automobile Club has planned out 16 events for the carnival to be held August 4 and 5.

The events are as follows:

Touring cars, gasoline, $3000 or less, regularly equipt, carrying five passengers.

Touring cars, championship, 60-horse power or less, regularly equipt, carrying five passengers, for the Atlantic City Bureau of Information Cup, value $500. Must be won twice for permanent ownership. Cup now held by A. W. Church, English Daimler.

Free-for-all championship, flying start.

Price handicap, gasoline, regularly equipt, carrying three passengers, $4000 scratch. Handicap one second for each $200 less in price.

Touring cars, $5000 or less, regularly equipt.

John H. Lyon's Cup, open to American touring cars of 30-horse power or less, regularly equipt, carrying five passengers, owners to drive. Must be won twice for permanent ownership. First winner, Charles Bacarach, Packard; second winner, Stoddard-Dayton; present holder, Ernest Lash, Packard.

Runabouts, gasoline, all types, opened to all runabouts, regularly catalogued and regularly equipt.

1-10 class, handicap, open to all cars that establish mark of 1-10 or better on the beach track.

Touring cars, gasoline, $3000 or less, regularly equipt.

Touring cars, gasoline, $1500 or less, regularly equipt.

Runabouts, gasoline, $1200 or less, regularly equipt.

Gentlemen's Roadster, handicap, gasoline, $5000 to $2500; $5000 scratch, one second for each $200 less in price. Owners to drive.

Time trial, gasoline, open to all.

Steam cars, open to all.

Foreign carriage, open to all foreign cars, 60-horse power or less, regularly equipt.

Stript cars, open to all cars. American manufacture.

The Atlantic City Show a Ten-Day Affair

It is announced that the show scheduled to take place in connection with the races and floral parade at Atlantic City, N. J., August 4th to 9th, will remain open until August 17, including two Sundays. The management have also arranged with Mr. Ball, the well-known decorator of the national shows, to furnish uniform decorations without cost to the exhibitors. Many prominent dealers have secured space and the show promises to be representative of the entire industry.

Missouri Automobile Association has appointed a publicity committee with Dr. S. Ed. Smith, of Macon, chairman. The committee will operate a press bureau and keep all the newspapers of the State informed on automobile happenings. The chief object of this bureau is to dispel the prejudices which exist in rural districts against the use of automobiles.

BY AN

R.-S. MOTOR BICYCLE

First Up Pike's Peak

First Up Mount Wilson

The R-S Slogan

"Built and Tested In the Mountains"

is full of meaning.

It means the power and ability to show the way up such long, steep, dizzy heights as Pike's Peak in Colorado, and Mt. Wilson in California. The R.-S. went up the latter mountain in 61 minutes; the only automobile that succeeded required three hours. The ascents were not promoted or prompted by ourselves and were made by private owners using stock models—the same kind you get for your money.

The difficulties of such climbs can be appreciated, as may also the sterling worth of the motorcycle that could perform such feats. Tests like these are the ones that count, and if you want a motorcycle which will fulfill all requirements of speed, dependability and economy, you will make no mistake in choosing the R.-S.

Send for catalogs. They are full of "meat."

Specially Built Racers Should Not Be Pitted Against Stock Cars

That there will be automobile races and competitive tests as long as the automobile continues to be the fastest vehicle known and the inborn love of vanquishing a competitor still to a large degree controls the actions of men, is not to be doubted. This being granted the pertinent question at once arises. What kind of racing events shall be encouraged by the manufacturers and the trade and what left to the sports and race meet promoters?

There are two reasons which usually act as incentives for manufacturers or dealers to enter cars in competitive trials; first and uppermost in their minds is the valuable advertising to be gained therefrom and second the information obtained, in regard to the suitableness of design and construction of the car, is considered. Unfortunately, the first seems to be the only one seriously considered by many, and race meet promoters take advantage of this fact to induce dealers and manufacturers to enter cars in events in which the cars are not properly classed and in which all too often some specially built freak machine carries off all the honors. Those who have been foolish enough to enter stock cars against such competitors are almost always the losers. Invariably the maker of the freak machine advertises that his car, not mentioning that it was specially built, beat all the other cars of whatever make and the general public who are not informed, take it for granted that the winning car was a regular model and of course the best machine.

It is surprising, indeed that so many of the trade can be induced to enter such nondescript competitions, when so little is to be gained, and so much may be lost.

What is needed above all is competitive tests of stock cars alone, endurance runs, sealed mechanism contests, and even races can be of material benefit to the industry, but let them be strictly between stock cars, exactly as sold to the public, all racing freaks being debarred from entering into such competitions. If there must be freaks let them race against each other. If anyone desires to enter stock models against such machines let them, but the rules should be so framed that it would be impossible to enter freaks against stock models.

A race without entries or with but one or two entries would be a failure, therefore if the manufacturers will refuse to enter their stock cars in those events which are not confined strictly to stock cars, more stock car events would be scheduled on race meet programs. The promoters must have entries to make their races a success, and they will schedule the races which will draw the largest entry list.

Valuable information and advertising can be secured from competition between cars equipt exactly as sold to the purchaser, and if hill-climbs endurance tests, sealed mechanism tests and race track contests are properly conducted there will be no lack of interest on the part of the purchasing public. It is time that the manufacturers and dealers take a stand and refuse to enter nondescript events in which the cars are not properly classified and all kinds of specially built cars are allowed to enter against regular stock models. Such contests are usually founded by race meet promoters whose sole object is to have an exciting contest from which the largest possible amount of gate receipts can be collected. The participation in such events by the trade, only furthers such schemes to the exclusion of legitimate stock car contests which would be of permanent value to the industry and also form the basis of much stronger and more valuable advertising.

Limit of Tire Endurance Reached

Altho much time has been consumed in vainly endeavoring to predict the ultimate form which automobile construction will reach, there are a few facts which can be learned from what is taking place at the present time. Among these facts in a prominent position is the difficulty that tire manufacturers have been

Hosted by Google

having, and are still having, to make tires which will stand the tremendous strain to which they are necessarily subjected when used upon the enormously heavy touring cars that the automobile manufacturers are now placing on the market. Machines which will seat seven people are to-day quite common, such cars weighing from three thousand pounds upward, and it is a well known fact that it is almost impossible to make pneumatic tires of any material which will resist the severe usage to which they are subjected, when such a weight as this is placed upon them. We believe that such extremely large and heavy cars are not absolutely necessary, and that the demand for them will never be very great. It is not uncommon for tires in use upon such vehicles to blow out after slightly over two thousand miles running, and altho this might be due to pumping the tires too hard and their subsequent over-heating or to minute flaws in the tire construction, the fact remains that the tires on these machines do not stand up as they should, and constitute a continual source of trouble and expense.

Automobile manufacturers have been constantly requiring more of tire makers, and it would seem that the limit of tire endurance has at last been reached. If satisfactory results are to be had, the automobile manufacturers must meet the tire makers half way by making a strenuous effort to cut down the weight of the cars offered to the public, and as the number of purchasers who can afford to operate cars capable of seating seven passengers, are very limited, there is even now, a tendency and one which we believe will grow stronger toward the construction of three general classes of cars, namely: two, four and six cylinder machines, each being of only moderate seating capacity and of the lightest possible weight consistent with durability, to secure the longest possible tire life. The small single cylinder machines are not included in these classes, as it is well known that there is very little difficulty at present experienced with tires on such small cars or even on the four or six cylinder runabouts, most of the tire trouble coming with the use of cars of large carrying capacity.

It is conceded that the tire question is the "bug-bear" of the automobilist, and believing as we do that the limit of tire endurance has already been reached, and in many cases exceeded as shown by the action of tires which are apparently flawless, it is evident that in order to reach a solution of the difficulty the automobile manufacturers, and not the tire makers, must be looked to.

In view of these facts, the automobile manufacturers of this country should combine in their efforts to reduce as far as possible, the weight of the large models, and co-operate in this respect with tire makers to bring about a reduction of the present tire troubles as seen in connection with the heaviest cars.

Worthlessness of Present Railroad Crossing Signs

It would be almost impossible for any thinking man to take even a short automobile trip thru almost any part of our country in which grade crossings exist, without realizing the fact that railroad crossing sign-boards as at present located, are absolutely valueless in nine out of ten cases to the automobilist. Any man with only normal powers of observation can see that he has reached a railroad crossing when he is within twenty feet of the same, and a sign-board will not make the matter any more clear to him, or be of any use whatever to him, when it comes within his range of vision, at the same time as an approaching train, often too late for his vehicle to be brought to a stop. We are not now speaking of speed maniacs, but of the mass of conservative automobilists who are every day in increasing numbers, using the highways of our country.

The present location of these warning signs is a relic of the past, when there were no vehicles or users of the highways moving at a speed greater than an ordinary horse trot, but conditions have now entirely changed, and in order to conform to the present state of affairs when a large per cent. of the highway users are traveling at a speed of twenty or twenty-five miles an hour, it is imperative, that at all but the most open grade crossings the sign posts should be placed at least two hundred feet from the railroad tracks on either side—a position which would give due warning to an approaching vehicle that so many feet beyond a railroad crossing might be expected.

Such a location of sign-boards would be of decided advantage not only to automobilists, but to all road users, for it is certainly true that where a roadway makes a sudden turn and crosses a railroad track, their present location is absolutely valueless to the horse driver, as well as to the automobilist. A sign in such a position is of about as much value as would be the blowing of the engine whistle after the victim has been run down.

It is to be hoped that all road users whether automobilists or not will combine in an effort to have the railroads co-operate with them for the general protection of the public, by doing away with the antiquated method now in vogue, of placing railroad crossing signs within a few feet of the crossing, and this effort should not be abandoned until the desired result of having the signs thruout our entire country placed at suitable distances on either side of all grade crossings, is accomplished.

Resolutions adopted by the various trade and owners' organizations requesting the railroad companies to move these signs a greater distance from the tracks would undoubtedly meet with ready compliance from railroad officials, all of whom appreciate

Hosted by Google

the necessity of adopting every possible precaution against accident.

It would also be of great advantage to have all of these signs thruout the country of a uniform color and design, so that the first glimpse of a sign would inform the driver that he was approaching a railroad crossing.

The Need for Commercial Car Agents and Sales Rooms

A summary of the automobile dealers in almost any of our large cities will show that so far there are very few agents with established show rooms or headquarters handling commercial cars. Even very few of the older established agencies for pleasure cars carry commercial vehicles also. Nearly all such vehicles are at present sold by representatives of the factory manufacturing the car, and very few of these men have permanently established show, sales rooms or machine shops.

This condition of affairs is working injury to the commercial car business, for factry representatives without definite headquarters or machine shops cannot properly obtain business and surely cannot suitably take care of customers after purchases have been made. The commercial field is exactly the place where proper attention and quick repairs or replacements are extremely necessary. A slight delay of a repair part for a pleasure vehicle can be tolerated, as it simply means an inconvenience to the owner or his family, but such a delay to a commercial vehicle part may derange a whole delivery system and entail endless expense, not to mention the dissatisfaction of customers, the avoidance of which is of vital importance.

If motor delivery vehicles are to be almost universally used and we believe that time is surely coming, now is the time that every make of such vehicles should have a well-established and permanent agency in each large city, sewing the seeds of the enormous business to be done in the near future. If the sale is not sufficiently large at this time to warrant a special agency, the cars should be represented by some well-known agent already established; in any case purchasers should be able to locate the different commercial cars at definite stands and should also be able to obtain parts within a reasonable time from such agencies. There is very little doubt that in nearly all of our large cities considerable more business could be done in the field of light delivery than is now being transacted. But to secure this business, aggressive agencies must be established whose representatives will go out after such sales instead of waiting for customers to come to them, as is usually done by the pleasure car agents, very few of whom employ outside men. The few manufacturers who are pushing the sale of commercial cars seem to be picking out the hardest possible customers first, namely, the department stores, who of all people have their horse delivery service highly organized and on as efficient a basis as possible. While an agent is inducing such a firm to buy one truck, and it sometimes requires considerable time to do this, as the introduction of motor delivery means the discarding of a large outfit and the installation of a new equipment, he might have sold fifty cars to individual or smaller merchants whose two or three wagon delivery methods are probably not over-efficient and to whom such a change does not mean the complete reconstruction of a large equipment. The sales to these smaller firms would soon cause the large stores to take notice and in due time adopt the up-to-date methods.

With any firm the purchase of a motor truck is strictly a business proposition and the fact that money can be saved either directly or indirectly by the use of motor trucks must be demonstrated to them. Motor delivery saves directly where the conditions of service are such that the actual expense by this method is less than by using horses —indirectly by added range, quicker and more satisfactory deliveries, more satisfied purchases or where the advertising value of such a delivery system is a decided factor. In order to demonstrate these facts to business firms it is absolutely necessary to have well-equipt and permanently-established agencies. These representatives should also on short notice be able to furnish competent operators as it is well known that most of the trouble experienced by beginners with commercial cars is due to incompetent drivers. A merchant with his first motor delivery wagon is much in the same predicament as a first user of the typewriter; he does not know just how to handle it. The agents for typewriters very soon learned that it was the part of wisdom to be able to furnish operators at any time and sales were made much more rapidly owing to the feeling of security and relief from responsibility which these operators inspired. The same thing is true with truck users and unquestionably many more sales could be made if the purchaser knew that at any time he could get a competent operator and be well taken care of.

Some at least of the truck and light-delivery car manufacturers realizing that now is the time to properly prepare the way, have negotiated with successful agents to represent aggressively their products and we believe that others will soon follow suit, attacking the commercial car sales problem by means of agencies with suitably equipt machine departments and permanently located sales rooms.

Cars or Drivers?

What is the object of motor-car racing? Is the desire and intention the development and exaltation of individual drivers? Or do the manufacturers go to an expense of $25,000 or $30,000 apiece to produce racing

Hosted by Google

cars to find out what makes the best car for high-speed work?

In the Vanderbilt Cup race the spectators individualized the drivers strongly and ignored the cars entirely. The daily press did the same thing, in some instances going to the extreme of printing the driver's names only, with no mention of carmakers' names at all.

Ostensibly the object of racing is to gain knowledge of what is best in motor car construction. In this case the course is made to present ordinary long distance touring conditions. The Vanderbilt Cup course gave many opportunities for accident; it was very hilly and crooked, and abounded with tire-puncture producers. Over such a road it was drivers before cars, and the press and public were not far wrong in "featuring" the drivers and paying practically no attention to the cars.

The object of racing is certainly not to improve drivers, but to improve cars, when racing truly reveals their faults.

Very clearly the first thing needed is a race course which will test the car, not the driver.

Shall the tire durability be tested by difficult turns, with abundant puncture producers everywhere present on the road-surface? The rubber tire is a comparatively weak structure. Its weakness is inherent, because rubber is a weak material, and cannot be made stronger. Yet a tire puncture came very near deciding the victor in the cup race. But it is absurd to say that car builders wish racing contests to be decided by tire punctures or tire explosions, any more than they want the driver to be the principal factor. This process of elimination brings us to a consideration of the chassis only, and makes car speed and car durability as a whole the elements for comparison.

What is wanted is a course on which the power, speed and durability of the individual racing car itself can be fairly shown, so as to obtain comparative results with various types of propulsion elements, so that builders can learn what is really the best material and construction for their cars.

Glidden Tour Scoring Defective

The system of penalizing is so based that it favors clubs with a large number of entries and works hardship to clubs of only a few entries, as the 1000 points given each club to start with, no matter with how many entries, is reduced in the following way: For each minute or fraction in excess of two minutes late at controls one-third of one point is reduced from a club of three cars, one-fourth of a point for clubs of four cars, one-fifth of a point for clubs of five cars, etc. Equal credit reductions for each dollar, maker's catalogue value, of repairs or replacements are given.

This penalty scale is evidently based on equal accident expectation, making 10 cars 10 times as liable to accident as one car, and hence, rightly, the 10-car club should only pay one-tenth the penalty of one car, or three-tenths the penalties of three cars, for the same fault. This is all right so far, but is wrongly applied as per these two "examples" quoted from the official Fourth A. A. A. annual tour booklet:

"EXAMPLE, PARTS PENALIZATION."

"A team of three cars, one of which replaces a spring valued at $10.00, will be penalized 3 1-3 points, which is one-third of one point for one dollar."

"A team of 10 cars, one of which should do precisely the same thing, will be penalized one point, or one-tenth of a point for each dollar."

"EXAMPLE, TIME PENALIZATION."

"A team of four cars, one of which is three minutes late arriving at a control, will be penalized one-fourth of a point for the one minute over and above the two-minute allowance. A team of eight cars, one of which is three minutes late arriving at a control, will be penalized one-eighth of a point for the one minute in excess of the two-minute allowance."

Like causes should produce like effects. The replacement of a $10.00 spring is just as big a fault in a 10-car club as in a 3-car club, and should penalize each club to the same extent; that is to say, should equally decrease the credit points of the two clubs. But by the example, each club having 1000 points start credit, the 3-car club has 996 2-3 points good after penalization for the broken spring, while the 10-car club would have yet 999 points good.

If each individual car started with 1000 points good, and each club was penalized one point for each minute late of each car and one point for each dollar of replacements, and then the credit remainder for each club at the end of the run were divided by the number of cars in that club, the quotients obtained would correctly and fairly show the comparative standing of the clubs.

If a 3-car club, having a total of 12 springs, breaks one spring, 1-12 of total, then a 10-car club with 40 springs should break 1-12 of 40—3 1-3 springs. Now say that each individual car has 1000 points start credit, giving the 3-car club 3000 points start credit and the 10-car club 10,000 points start credit. When the spring breaking charges were penalized at one point deduction for each dollar, the 3-car club would have 2990 points credit and the 10-car club, breaking the same percentage of springs, would have 9966.67 points credit, and dividing club credits by numbers of club cars would give 2990 divided by 3, quotient 996.666, and 9966.67 divided by 10, quotient the same, save for the repeating decimal, 996.667, making like causes produce like effects which is as near as human law can come to justice.

The Hower trophy penalization deals with single cars only, 1000 points individual credit, and one point off for each late minute or dollar of repairs, which is equally fair for all parties.

Hosted by Google

The fourth annual Glidden Trophy con-
est began at Cleveland, Ohio, at 7.00
. M., Wednesday, July 10, whence the
ars ran to Toledo, Ohio, and on Wed-
esday, July 11, the run was from Toledo
o South Bend, Indiana, and Friday's run
as from South Bend to the Auditorium
nnex, Chicago. The general story of
ese first three days follows:

As with all of the "3-A" functions, ac-
urate information regarding this Fourth
lidden Tour is very difficult to obtain,
nd recorded facts are persistently elusive.

The original scheme of these Glidden
ours was meritorious, inasmuch as it stim-
lated participation in an extended touring
ontest by the foundation of a permanent
ophy, and the promised publication of ab-
olutely accurate records of the perform-
nce of each contesting car on the road,
ut up to this 1907 competition the "per-
ect score" awards have been made, in
ome instances at least, to cars which had
eplacements of such important members
s springs, axles and even motor cylinders,
o that the Glidden testimonial was by no
eans a warrant of absolute long-tour
eliability for the car which proudly dis-
layed it.

The extended tour car test would give
ighly valuable comparative conclusions if
e passage of a lot of cars over the same
oad the same day placed each and every
ne of the competitors in exactly the same
ifficulties on the route, but this can never
be, and accidents from exterior ca
will always greatly influence the final
sults of any extended touring contest
long as the course covered is not kept
solutely clear and free from everything
everybody except the competing cars,
even then the weather, as a blinding r
storm, for example, at a dangerous p
on an unknown road, might bring disa
to the very best car.

However, taken all together, the l
road run is the best car test there is,
the results will always be largely affe
by chance circumstances, for the most
beyond the control of the contestants

This influence of chance was illustr
in the first day's run, when a boy came
of a dust cloud directly in front o
Welch car, and the driver sent his forw
wheel against an iron bridge support ra
than run over the youth, and was
penalized for axle repairs. The Welc
a high-powered, low-weight car, well b
and has small expectation of axle fail
yet this particular Welch car in this
scored an axle failure very early in
tour.

To obtain identical running condit
every car must be at the same place on
same road at the same time, which
manifest impossibility. But in spite of
part played by chance in the results
tained the long road-run, as before sta
is the best car test available, and a 1
mile clean score is well worth the th

Digitized by Google

ıe 1904 A. A. A. run was from New k to the St. Louis World's Exposition. re were 77 entries, 66 finishes and no e or trophy.

ıe Glidden Trophy was offered by rles J. Glidden, on the occasion of the A. A. A. run, round trip, New York, tford, Bretton Woods, Concord, Wor- er and return. Percy P. Pierce, driving erce car, received the trophy. There 34 starters and 27 finishers.

or the 1906 tour two trophies were of- d, the Glidden and one by Paul H. ning, chairman of the A. A. A. Touring rd, and the course was longer, Buffalo York State towns to Lake Cham- n, Montreal and Quebec, Canada, fin- ıg at Bretton Woods. The Glidden phy went again to Percy P. Pierce, ing a Pierce car, and the Deming Tro- to C. W. Kelsey, in a Maxwell car. 1906 A. A. A. tour had 74 entries and tarters, eight of which were non-con- ants, and 30 finishes, with 13 "perfect es" which took no notice, according to ılar estimation, of repairs by the way.

HE PRESENT 1907 GLIDDEN TOUR.

"team interest" feature has been in- uced by awarding the custody of the den Trophy to a club instead of to an vidual, and Touring Board Chairman 3. Hower offers a trophy to be award- he entrant of the runabout making the individual score.

he entrance fee is $100, with 82 entries, ded into 47 Glidden contestants, 14 ver contestants and 16 non-contestants. eems that some entrants were early or did not start, as the "official" list tains the names of 115 proposed start- and cars, while it is also "officially" ed that only 74 A. A. A. tourists began run at the Hollenden Hotel, Cleveland, 10, 1907.

REGULATIONS OF THE TOUR.

he A. A. A. distributed, gratis, a book- of 85 pages, containing complete in- nation as to this 1907 tour, including os and minutely detailed road descrip- s with local illustrations. This A. A. tion contained is here condensed.

The control of the tour is in the Tourin Board, Frank B. Hower, chairman; Dai H Lewis, secretary; James P. Dill, L. E Myers and Philip S. Flinn, there being n appeal from Board decisoins.

The cars supplied free of cost to th A. A. A. are Pierce 6-cylinder 65-H. P. ca Pathfinder, a Pierce "official" car, a Max well-Briscoe "official" car and a Premie C "official" car. Spooner and Wells, Ne York, are official photographers for th tour.

DAY'S ROUTES, 1907 TOUR.

July 10	Cleveland, Ohio—Toledo, Ohio	121 mil
11	Toledo—South Bend, Indiana	166.3 mil
12	South Bend—Chicago	101.1 mil
15	Chicago—South Bend	101.1 mil
16	South Bend—Indianapolis	147.5 mil
17	Indianapolis—Columbus, Ohio	174.2 mil
18	Columbus—Canton, Ohio	151.4 mil
19	Canton—Pittsburgh, Pa.	99.8 mil
20	Pittsburgh—Bedford Springs	97.2 mil
22	Bedford Springs—Baltimore, Md.	140.2 mil
23	Baltimore—Philadelphia, Pa.	171.9 mil
24	Philadelphia—New York City	98.2 mil
Total		1,570 mil

The cars will be checked at Jersey Cit Court House, cross by Pennsylvania ferr to New York and form a line on Twenty fourth street, and will then run up Broa way to be officially checked out at Ce tral Park. No certificate will be given not checked out at this place.

"CONFETTI."

"The entire route of the tour will b marked with confetti, distributed by pil cars, which will leave early every mor ing."

The route has, so far, been so marke and more too, as the pilot in more tha one instance made the wrong turning fir and marked it with conspicuous bunch of cut paper and then went back a marked the other correct turning. Th contestants made both turns, too, but di not mark the double event with cut pap or anything else fit for reproduction print.

Every car carries its own baggage, a as no one is allowed to touch the ca from checking in to checking out, the c foot spaces have been sights to see, a

Digitized by Google

the baggage handling and storing at the hotel doors, after checking out for the start, has not made for security of property nor comfort of individuals in transit.

The advance hotel work was done by Thomas Cook & Sons, and accommodations were anything but satisfactory in many places. But this is probably to be expected to a greater or less extent in such a tour.

FROM CLEVELAND TO TOLEDO.

The writer reached the Hollenden, Cleveland, Tuesday, July 9, and found plenty of A. A. A. tourists already there. The next morning, after breakfasting at 6.00 A. M., and finally checking out, we started from the Hollenden at 7.40 A. M.

The notable feature of this day's run was the great and cordial interest displayed everywhere along the route, by all classes, men, women and children alike. It was a triumphal porcession of waving hands, smiles and good wishes from every one.

Personally, the writer suffered severely from want of goggles. In many places the dust lay inches deep on the dirt roads and sometimes spurted out of the ruts like water. Much of the way it was impossible to see a car-length ahead, but as every one held about the same 25-mile pace there was only one accident, caused by a boy appearing in front of a Welch car in the dust cloud, as previously mentioned. Our car reached the Toledo control at 1.30 without noteworthy incident, and with 40 minutes to spare. After lunch the writer provided himself with goggles.

FROM TOLEDO TO SOUTH BEND.

We checked out at Toledo, 7.12 A. M., Thursday, July 11, and headed for South Bend, Indiana, 166.3 miles. Heavy rains in the night had changed long stretches of good natural soil road, over which good time could have been made the day before, into almost impassable mud holes. We had no chains on our wheels, and as the car was very heavy the hind wheels constantly tried to pass the front ones, first on one side and then on the other, so that we had to follow the deepest ruts to keep out of the ditches. The day was cloudy, with several sprinkles of rain and one sharp shower, which stung our faces as we drove against the wind.

The same cordial reception was given everywhere, with only one solitary instance of fault-finding by a horse driver. This was a very hard run in every way, both for cars and drivers, owing to the almost impassable condition of the roads and two serious accidents occurred. Shortly after passing out of Toledo Kenneth R. Otis, of the Cleveland Automobile Club, while driving his own 6-cylinder Pierce, was upset by the giving way of an embankment as he was passing another car. Himself, his wife and her sister were severely injured. Mr. Spooner, official photographer, and Noonan, the Otis driver, were passengers in the car at the time, but were uninjured. Miss Rollins and Mr. Otis were both pinned under the machine, but assistance was immediately given, and they were extricated.

Mr. T. J. Clark, of the Chicago Automobile Club, was driving his own car near Bryan, 63 miles from Toledo, when it skidded and turned once and a half over. E. W. McGookin, Chicago; Peter R. Fehey, of Cleveland, and George Hunt, Clark's driver, passengers in Clark's car, escaped injury. Clark was dragged from the car as it was turning over by Dr. Andrew Callahan, of Buffalo, who was in the official "Red Cross" car close behind. Mr. Clark was severely cut about the face, and sustained a fracture of the lower jaw and two ribs.

The Otis car was wrecked, but the Clark car, in spite of a broken steering wheel, was driven into South Bend by George Hunt, Mr. Clark's driver.

Both these accidents occurred while owners were driving on very dangerous roads and carrying their own drivers as passengers.

FROM SOUTH BEND TO CHICAGO.

From the hotel Oliver, South Bend, we checked out at some time after 8 A. M. for a short run of only 101.2 miles to Chicago, which we expected to make in three hours at most, as we had a 50-mile car and the roads were good. The same cordial spirit was everywhere shown, the day was fine, roads fair or good, no mud, no dust and everything joyous. The route was changed to Michigan City, north of Valparaiso, and we were well in the lead, a few miles west of Michigan City, 30 minutes in advance of our own schedule, when our commutator began to cut and short-circuit. Proper detail construction would have let us change commutators in 15 minutes, as we had another with us. As it was, a broken set-screw, and a screw dropt down beside the cam shaft, so that everything had to be pulled apart under the motor. This held us in one place for five hours and cost us 250 points penalty. We made from 40 to 50 miles after we were finally right, and reached the Auditorium Annex some time between 6 and 7 P. M., seven hours behind our own expectations.

We had past pretty much everything in front of us before reaching Michigan City, where our mishap occurred, and had the pleasure of seeing them all pass us as we were broiling in the July sun.

Saturday and Sunday the tourists who had no stories to write rested from the horrors of the Toledo-South Bend run, which will never be forgotten by any one who experienced them, as a car running crosswise of a narrow road, in deep mud, with deep ditches on each side, and no chains on the wheels is something to think about.

Hosted by Google

CHICAGO TO SOUTH BEND.

The tourists started out again on Monday morning, after a two days' rest in Chicago, the cars checking out from the First Regiment Armory shortly after 8 o'clock, with an overcast sky and every indication of a severe storm. The schedule was one of six and a quarter hours. Before we got fairly out of the city limits, rain began to fall, and there were intermittent showers and thunder-storms during the entire day. In all 69 cars left Chicago this morning.

To-day a new method of scoring was introduced by Chairman Hower. Each driver was handed a cardboard placard with a number upon it, which denoted the order of the start. The rule was that no car was to pass a car carrying a lower number than the one carried by the car approaching from the rear except when the car in advance was stopt or was proceeding at a very slow pace. Then the overtaking car could pass, the drivers exchanging numbers.

The end of the day's run, the fourth day, shows 28 clean scores for the Glidden Trophy out of 37 contestants still running. and seven clean scores out of the nine contestants for the Hower Trophy. The standing of the clubs to-night, at the end of the run from Chicago to South Bend is as follows: Pittsburg Automobile Club, 1000 points; Automobile Club of Buffalo, 1000; New York Motor Club, 965.6; Cleveland Automobile Club, 744.1; Westchester Motor Club, 664; Chicago Automobile Club, 637; Automobile Club of America, 497.5; Automobile Club of Detroit, 457.5.

SOUTH BEND TO INDIANAPOLIS.

About nine o'clock a downpour began which made the clay roads very slippery, but, on the whole, the roads were better than had been expected and many of the tourists rode in ease with their feet perched upon the dash.

OVATION GIVEN BY FARMERS.

The most noticeable feature of the day's run was the cordial reception accorded by the farmers, who gathered in groups with their families in wagons by the roadside, and cheered the mud and dust-covered caravan.

Fortunately the roads were hard and after rolling along over the roads for a change, instead of ploughing thru them. Indianapolis was reached and the cars were checked in and placed under the care of the police in the circle about the public monument. There were all kinds of entertainments given by the hospitable Indiana Automobile Club.

The pacemaker system works wonders, and there was much less reckless speeding and no accidents of a serious nature.

THE 174-MILE RUN TO COLUMBUS.

This day's run was looked forward to with uneasiness by most of the contestants, altho nine and one-half hours were allowed by the schedule. The checking out in a drizzle did not tend to raise the spirits of the company.

In the main, however, the roads were good, the national highway being a straight macadam turnpike with only infrequent rough spots.

Out of Springfield there are a succession of ugly water breaks, but for several miles they had been marked with red flags by the Springfield Automobile Club.

The welcome by residents along the road was as hearty as yesterday, and many bouquets were thrown at the passing cars.

For the Glidden Trophy the Buffalo and Pittsburgh Clubs still have perfect scores.

COLUMBUS TO CANTON.

The time allowance for to-day's run to Canton of 152 miles was eight hours and forty-five minutes. The trip was rather trying as for most part it was over clay roads and there were many steep hills crost by water breaks, but the weather was good. The confetti car once more took a wrong road with the usual disasterous results, disastrous at least to the drivers' peace of mind. The score car, a non-contestant, broke part of the steering gear and coasted gently into the old State canal of Garfield fame. No further damage was done—the car was pulled out. The 30-H. P. Walter car, driven by Ed. Walter, after taking a bridge near Beidler at good speed was unable to make the sharp turn following without hitting a telegraph pole, so ploughed into an open field. No damage was done, however, and after being hauled out the car proceeded and checked in on time. The close contest between the Buffalo and Pittsburgh teams, each with perfect scores, was marred to-day by Gus G. Buse, of the Buffalo team in his Packard, losing 42 points and leaving the Pittsburgh the only perfect score team. This team will start first on the run to-morrow, so as to enter their own home place, Pittsburgh, first of the line.

CANTON TO PITTSBURGH.

The run of 100 miles to-day from Canton was for about half the distance over mountain roads, the roughest yet encountered.

As a result of the first day in the mountains several springs were broken, some axles bent and a number of cars failed to get in on time. The perfect score Pittsburgh Club team were received enthusiastically by large crowds on the streets and many buildings were decorated. Two bullets were fired by unknown parties into the back of R. H. Tucker's Royal car to-day. Four more clean score cars were penalized, owing to the very bad going, leaving 20 perfect score cars. Lozier No. 25 broken spring and delay 57 points. Gaeth No. 28 3 points. Haynes No. 55, 2 points. I. C. Kirkham's Maxwell No. 41, 37 points. Four other cars lost points, but had already been penalized. For the Hower Trophy there are 5 perfect scores. The contestants had but six hours to finish inside the time limit, which necessitated a pace too rapid for safety. The consistent running of the small two-cylinder cars has been a revelation to many.

PITTSBURGH TO BEDFORD SPRINGS.

The run this day of 98 miles over the mountains was the most severe yet attempted and many perfect score cars were penalized. The Pierce Great Arrow No. 21, of the Pittsburgh team, was delayed, owing to the throwing out of one of its occupants and was one hour and 32 minutes late, thus spoiling the perfect score of the Pittsburgh Club. Buffalo now leads with 981 4-5; Pittsburgh second, 977½. For the Hower Trophy the 35-H. P. Stoddard-Dayton, of G. F. Smith, and H. K. Sheridan's White steamer, are the only perfect score cars. Poor gasoline obtained at Ligonier caused several cars delay and penalization.

BEDFORD SPRINGS TO BALTIMORE.

The run to Baltimore thru one of the most picturesque parts of the country, was apparently enjoyed by most on the tour and much less difficulty was experienced and most checked in on time. The tourists were bothered by the large number of toll gates which were in places not over a mile apart. The White and Stoddard-Dayton are still tied with perfect scores for the Hower Trophy. The scores of the Buffalo, Pittsburgh, Cleveland, Westchester and A. C. A. teams remain as yesterday, Buffalo being in the lead.

BALTIMORE TO PHILADELPHIA.

The run to Philadelphia of 171 miles with fair weather, good roads and a time allowance of 10½ hours was really easy and was one of the few days of pleasure on the tour. There were few accidents and no perfect scores spoiled. The Haynes, No. 55, which up to this time had but two points against it, at Malvern in the afternoon broke the rear axle near the right wheel and had to withdraw. There were six cars arrived late, among them Mrs. Cuneo, who had spring trouble but she was heartily cheered as she drove up to the Hotel Walton at 11.45 that night. The Welsh stopt at the Autocar factory with a broken crank shaft which necessitated its withdrawal.

The Deere broke two front springs but arrived at 9.30 and the American Mors was reported with a broken spring about 20 miles out. The tie between the Stoddard Dayton and the White Steamer for the Hower trophy still holds and as to those running perfectly there is some question as to the method of award if both reach New York City with perfect scores.

At the Walton a drawing by the perfect score

Hosted by Google

cars for position in the line after the official and confetti cars when entering New York City resulted as follows: 47, 39, 22, 39, 11, 104, 14, 17, 54, 49, 9, 48, 42, 19, 27, 108, 3 and 50.

The entry into Philadelphia was marked by a most cordial welcome. From Malvern to the city there are numerous toll houses the frequent stops at which would have been very annoying but for the fact that each car was presented with a flag by the "Press" of Philadelphia, allowing it to pass all the toll gates free. This courtesy was highly appreciated by the tourists. Enthusiastic crowds viewed the dust-covered cars as they sped through the city. The cars for the most part arrived ahead of time and after the checking in were housed under police guard in the court of the City Hall. After the scores had been completed the tourists were driven in private and sight-seeing cars to the Majestic Hotel. The recent gorgeous illuminations for the Elks were in full blaze for the night, in honor of the tourists. As joint hosts the Quaker City Motor Club, the Philadelphia Automobile Club and the Germantown Automobile Club royally entertained the guests. At the Majestic after an address of welcome by Mayor Reyburn and short addresses by Glidden and Chairman Hower there was a vaudeville show and refreshments were served.

PHILADELPHIA TO NEW YORK.

At seven o'clock sharp about 50 cars checked out for the 98-mile run to New York City or rather to the City Hall, Jersey City, as the cars were to check in at that place. The running time of 5½ hours proved ample and all the cars checked in on time, the scores of the clubs remaining as at Philadelphia. This makes the Buffalo Club the winner by 4 3-10 points better score than the Pittsburg Club, a close second.

The tie between the White and Stoddard-Dayton for the Hower trophy was not settled by today's run.

After leaving Jersey City by the Pennsylvania 23d street ferry the cars formed in parade line at 24th street. Chairman Hower's car led and was followed by Mrs. Cuneo who was given this place by courtesy of the tourists, the press car, which had acted as a confetti car distributing each day about 100 pounds to mark the route, came next in line and was followed by the official car. The perfect score cars, 18 in number, formed the second division, following in the order of the numbers drawn at Philadelphia, Walter White leading. The cars were joined by many friends whose cars lined in behind and the procession proceeded to Broadway and 58th street, thru to 5th avenue and around the Plaza Circle. The lineup on 59th street toward the park was then photographed and then immediately disbanded. The tourists were anxious to wash up and don civilians clothes once more, all tired but proud of the performance of the cars. Many of the mud and dust covered cars were immediately placed at the curb in front of their respective agencies. The line of the parade was crowded with people to witness the finish of the most strenuous try-out ever given the American automobile.

At 8 o'clock at the Hotel Astor the official scores were read and a silver loving cup presented to Mrs. Cuneo by 110 of the tourists. The cup will be suitably inscribed. A form of certificate will be given to each car which completed the tour. Details of the method of running off the tie for the Hower trophy have just been settled. The cars will start from the A. C. A., N. Y., Monday, July 29th for Cleveland accompanied by Chairman Hower and a confetti car and from Cleveland will continue over Glidden route until one is penalized.

It is expected that the cars may cover a portion or all of the route again if necessary. Mr. Glidden expressed himself as well pleased with the outcome of the tour, and was particularly impressed by the hearty and enthusiastic reception given the tourists thruout the entire run. During the evening a congratulatory telegram was received by Mr. Glidden from Judge Hotchkiss, president of the A. A. A.

The performance of the few small powered low priced cars has been a surprise to many. The Reo car No. 33 which finished with a perfect score, starts to-night for a non-engine stop run to the Jamestown Exposition.

It is a noticeable fact that there are no air-cooled ars in the tour this year, altho the Marmon and Knox made perfect scores last year. The Frayer-Miller, however, had intended entering the car used in the 24 hour endurance race but were unable to get it ready in time. The following is the official score of the clubs and individual cars as given by the committee:

Considerations of Motor Car Elements

HUGH DOLNAR.

(The name of the writer of these considerations is well known to our readers as a describer of new cars, and his extended experience as a machine designer and constructor gives value to his deductions and suggestions. Should any of our readers dissent from the conclusions reached in these articles, the columns of the Journal are open to all, in the full belief that free discussion and interchange of opinion is the shortest road to perfection.—Editor.)

Starting Devices and Self-Starting Motors

The ordinary form of gas engine in exclusive use for motor-car driving has no reservoir of power corresponding to the steam-engine boiler and is therefore wholly inert when stopt and cannot be made truly self-starting, tho common usage speaks of gas engines fitted with mechanical starting devises as "self-starting" meaning that the motor can be started without much muscular exertion on the part of the driver, who has merely to make such changes in the motor as will enable it to make use of some starting device other than the strength of the driver applied directly to the starting crank.

The hand starting-crank is commonly applied directly to the end of the motor crank-shaft, either with or without first relieving the piston of part of the compression pressure. With the piston diameters now in use considerable strength is required to start the motor with the hand crank, even when equipt with some one of the many forms of compression-releasing devices which have been invented, and the violent muscular effort required often leads to painful accidents to the one who is turning the crank, even when the cranking proceeds in normal form, as the starter stands close to the radiator and in stooping quickly is liable to severely injure his head by striking it against the radiator edge or cap. Instances have been known in which the cheek of the starter has been laid open, and the writer saw one unfortunate cut his right ear in two on the radiator cap edge, while a recent newspaper paragraph told of a starter's tongue being bitten in two in this manner.

The more common form of accident to the starter comes from "back-firing," as it is termed, meaning the too early firing of the charge, which drives the crank violently in a direction contrary to that in which the starter is turning and so sprains the wrist, which is the most common effect, or perhaps may break the bones of the hand or the arm. Every one who is much about motor cars can recall a long list of more or less serious disablements from back-firing. The writer witnessed the breaking of the bones of the hand of a powerful mechanic, and is personally acquainted with an expert driver who had both bones of his right forearm broken by a starting crank, in such fashion that several successive surgical operations and thirteen months in the hospital resulted, caused, of course, by failure to be certain that the spark-timing device was retarded to a safe position before attempting to start the motor.

It is easy enough to invent linkages to operate in combination with the starting crank as it is applied to the motor crank-shaft for starting, which will release the compression and retard the spark-time so that hand-cranking becomes comparatively easy and safe, and many such arrangements have been applied, but not one has been so suitable and so well-built and certain in operation as to bring it into common use, and some most painful accidents have resulted from the failure of these automatic starting safety devices to work as intended. Because of the added complication and the failure to give satisfactory results, these safety starting devices have come into emphatic disfavor, and are very seldom fitted at present, it being thought better to make the starter look to his own convenience and safety by manipulating the compression relief cocks and regulating the spark-time himself, before beginning to crank the motor.

SELF-STARTING MOTORS.

To make a gas engine start without turning the crank-shaft by hand, some reservoir of force or pressure must be had as a source of power, and some means of applying this power to cause the motor piston or pistons, at least, to move, must be supplied.

A cap containing an explosive has been tried, which when fired would drive the piston and give the fly-wheel sufficient momentum to make the motor start. A comprest air reservoir and air pump worked by the motor have been used in several ways, such as driving an independent air-piston linked to a rack coacting with a pinion fixt to the crank-shaft, or driving two of the cylinders of a 4-cylinder motor and thus causing the other two to begin to work as gas engines, the motor is then restored to its normal form and the two cylinders which are working keep the engine running until the first two cylinders draw gas, or by a third method, working all four cylinders as comprest-air driven motors at first and then changing them all to operate normally, depending on the momentum of the fly-wheel to start them working as gas engines.

Menges, in the "Crankless" Harrison car, first charged all four cylinders with pure air, then added acetylene gas to this pure air charge and fired it and instantly changed the motor back again to normal form, causing the first charges of air and acetylene gas to start the motor, which then worked with normal charges drawn thru the carburetor.

When the working cylinders are used in any but the normal cycle, the valves must be operated to suit the change, and this condi-

Hosted by Google

tion involves a change in the cam-action, either by bringing an entire different cam-shaft and cams into action, or by shifting the regular or normal cam-shaft endwise, so as to work the valves by a different set of cams.

Various arrangements of levers, straps, chains and ratchet and pawl actions have been employed to enable the driver to start the motor without moving from his seat in the car, but such arrangements depend wholly on the power of the driver's muscles, and are not really self-starters at all, but are only modifications of the hand-starting mechanism.

Besides the Menges-Harrison Self-start, the writer is aware of but one other American car motor which deserves to be classed as self-starting. This is the "Triumph," in which pressure from one working cylinder of a gas-engine car motor is delivered to a storage tank and held there at a pressure of from 100 to 125 pounds per inch, ready to start the motor. When the motor is to be started the cam-shaft is moved endwise, bringing eight starting cams which move the working cylinder valves into position, so that the rearward pair of cylinders of a 4-cylinder motor can work as comprest air motors and so start the other pair of cylinders as gas engines; then the cam-shaft is moved endwise back to normal position and the rearward pair of cylinders are then driven by the forward pair working as gas engines, so that they, too, begin as gas engines. The Triumph pressure tank is not arranged to be filled with compressed air from an exterior source of supply, and therefore an ordinary hand starting-crank is fitted, by which the motor may be started in the usual manner, after which running of the car on the road establishes an air-tank pressure, so that it is not necessary to crank the motor often for starting because there will commonly be sufficient pressure in the air-tank to start the motor in the manner specified.

There is no doubt whatever of the great desirability of a really good, practicable and thoroly reliable starting mechanism for car-motors, and because a self-starting motor is so much needed it is certain that it will be produced, if not already to be found in its best form.

The results of a long trial run with the Triumph self-starting motor are told in another place in this issue of the journal. This self-starter is comparatively simple, is not very costly and does not at all interfere with the reliability nor the power of the motor. The Triumph self-start appears to be about as good as can be done without the use of a separate air-compressor and air cylinder for turning the crank-shaft, which is what must be used, so far as is now seen, if the turning effort is not given by using some of the motor cylinders for imparting to the crank-shaft its primary revolutions.

Commercial Components

Shall each separate builder of cars produce structures of marked individuality, differing in important particulars from anything made by anyone else and original in every principal detail?

No car builder does this, as all the makers buy some parts of their cars from suppliers to the trade, but there is a broad originality possible in principal components and this originality, of greater or less extent and scope, is, of course, advertised as a mark of superiority in intelligence and mechanical ability.

The commercial supplier of a certain component, as, say, the rear axle and front axle of a motor car, reaches a much greater number of individual users than can be found as purchasers of any one make of motor car. Every single one of the users of a commercial component is sure to report all faults to his supplier, the maker of the car, who in turn is certain to report to the component maker, who is thus informed of the actual service done by his work all over the country, under all conditions of road and by all classes of car purchasers and drivers.

It also appears to be certain that a car built up from approved principal components cannot greatly disappoint the purchaser, provided that these good principal elements are assembled by a constructor of sound judgment who will see to it that the auxiliary details, designed and constructed by himself, are efficient in form and are well built.

Probably as time passes cars will become divided into a very few well-established types; if this should prove to be the case the maker of commercial components will dominate the final situation because all cars will be assembled of parts each made by the best specialist, who must always excel the best general constructor in perfection of product.

Aluminum vs. Grey Iron

Is aluminum a necessity in motor-car chassis construction? This important question is answered in emphatic negative by the fact that first-class cars are made with grey-iron crank boxes very little if any heavier than those of aluminum, which shows that the gear box can also be made of grey iron and yet fill all requirements, but, of course, gives increased weight. Grey iron can be had in any desired quantities, and if handled under expert direction can to a certain extent take the place of aluminum castings in motor car construction without excessive weight additions, and with added "reliability" as far as screw threads are concerned. It is pretty certain that a very serviceable car for the average user can be made of ordinary steels and grey iron, with all working joints hardened, for about 50 per cent. of the flat cost of what is now regarded as high-class in motor-car production, or 35 to 40 per cent. of the flat cost of the very best cars now made, where chrome nickel steel and aluminum castings are used freely and that the ordinary materials, by skillful designing and treating of all working parts can be made as satisfactory to many users as the car built of high-grade material thruout.

Steering Actions

Always after writing the story of a car with the designer of the car, there comes an illuminating talk between the designer and the describer, in which the designer goes over the reasons for his changes, and tells why he has not built his new model as he believes it should have been built.

The story almost invariably turns on some sales agent's catch-word, which has become impressed on the motoring public mind as representing an indispensable requirement of the really good motor-car, to the extent of influencing the choice of the prospective car-buyer.

After losing sales steadily for a season because he has dared to cross the catch-word accepted as final for some detail, the designer becomes very ready to meet the catch-word requirement in his next season's design.

One of the catch-words now fully committed to memory by the motoring public is "Irreversible Steering." Of course, the term is not exact, as a steering gear not reversible could turn the car in one direction only, but "Irreversible Steering" is a good mouth-filling expression, and is accepted as meaning "Locked Steering Action," in which no wheel-shock can move the steering wheel.

Kelly, of the Wayne, said, "Yes, I have abandoned the rack and pinion steering in favor of the right and left hand external and internal screw threads and double-crutch globe-end steering bell-crank. That is the best steering action yet, in my opinion, big wearing surfaces and perfect wear take-up. I don't believe at all in the worm and worm-gear action, which has only point bearings, and must wear fastest in the "straight-ahead" engagement, and which cannot have the lost motion taken out by any adjustment yet shown. The rack and pinion costs less, has plenty of engagement surface area, and naturally takes the cross-wise main steering-rod, and has a hundred times the life of the worm and worm-gear, and if the rack and pinion are cut round top and bottom teeth, the pinion can be forced hard into the rack, teeth bottoming, and do away with all lost motion. We traded in one of our first cars, that had been run hard and all the time for two years, and the rack and pinion steering action was good as ever, no lost motion at all. But we lost a lot of sales because we could not claim "irreversible," tho you never feel a front-wheel shock with the rack and pinion steering, and so I am putting out this new screw and nut steering action for 1907, to meet a silly catch-word—"Irreversible steering."

The Bartholomew "Glide" man said, "Oh, yes! you needn't laugh! we took out our compound spur gear steering action that was fourteen times as good as any worm and worm-sector, and put the worm and sector right in for 1907, and you bet we don't lose any more sales because we haven't got 'Irreversible Steering.' Yes, we are 'sliding gear' for 1907, too. Our big planetary was splendid, change any old time any old way, soft as silk and smooth as butter, but if folks want to buy 'whir-r-r-r' sliding gears we are just smart enough to make and sell them."

Smith, of the "Great Smith," of Topeka, said, "Oh, yes, it's sliding gear all right. Yes, most of the time it changes all right—of course, when the gear teeth come square end to end they don't mix worth a cent, and our planetaries never gave us any trouble at all, but folks won't stand for 'planetary' any more, so we are 'sliding gear.' I wouldn't drive a sliding gear myself." "Yes, I am sticking to my spiral spur-pinion and sector steering, spiral internal sector teeth. Of course, the action is all the same as a plain pinion and gear sector, only the spiral makes it smoother, and when the buyer asks if it is 'irreversible' we just show him the spiral pinion, and that looks like a worm, and the leverage is enough to keep the wheel shock from being felt on the steering wheel."

Blair, of the "Craig-Toledo," said, "Do you suppose I would put that single-point surface-bearing worm and worm-sector in a car I built? I guess not. I put in the quintuple thread screw with the take-up trunion nut, and I've got 3⅝ square inches of thrust contact. I can keep my steering gear perfectly tight, and, of course, it is near enough 'irreversible' to claim it. Anyway, you can't feel anything on the hand wheel."

All of which means that the catch-word must rule, after the agent has taught the public the parrot phrase.

STRUTS AND TORSION ARMS.

There is a very surprising difference of opinion among car designers as to the value of the torsion arm, as well as that of the struts. Both large and small cars are made without struts and without torsion resisting arms. In other case the torsion arm is used in connection with two struts from the rear axle to the chassis frame sides, and sometimes four struts are placed two from each axle to the middle of the frame sides, or to some other point. There are also various triangular axle braces fitted, which have the axles as bases and are jointed to the chassis frame girts.

If the torsion arm is not placed, then the rear side springs must resist the rear axle torsion, and if the struts are omitted then the front part of the rear side springs must transmit the driver thrust to the car. If the car does as well without the torsion arm and struts it is difficult to understand why these members are placed, and if the torsion arm and strut perform valuable functions it is difficult to see how they can well be omitted.

Steering Gears and Axles of Small Cars

Recently the writer was asked his opinion of a new car of the large wheeled type. The machine in question was the first one of its kind, 750 pounds, $650; 40 inch wheels, fitted with solid tires, and, as I remember it, 72 inch wheel base, very roughly built, with a pair of opposed cylinders under the seat, friction

Hosted by Google

speed change, side chains to the rear wheels, and was said to show 14 B. H. P.

The writer viewed this new high wheeler with scant approval and spoke with entire candor: "Ten inches added to the wheel-base would cost very little more and would vastly improve the riding qualities. The front and rear axles are both very light, far too light for safety, and the front axle yokes have not nearly opening enough, and the axle steering arms should be twice as long as they are. The steering gear is bad and the axles will not stand grief." The designer of this new high-wheeler at once replied that the which were only about five inches, were abundantly strong, that the steering arm radii, which were only about five inches each, were plenty long enough, that the car was safe, had been driven 700 miles and had shown no weakness anywhere, and could easily make 40 miles an hour.

Observing the designer's confidence, the writer refrained from added speech and took his seat in the new car for a trial run. The car had plenty of power, and rode fairly well on its four half-elliptics on smooth macadamize, but jounced over car tracks and had all the bounce its short wheel-base called for on bumpy road surfaces.

The designer was disposed to make speed, and the writer held on apprehensively, watching the rims of the front wheels, and the driver's crude handling of the car with mental as well as physical disquiet. The loose board deck of the after-body displaced itself while the car was hopping over some bumps which better driving could have avoided, when suddenly the car swerved very sharply to the right, headed straight for a low bank, which it partly mounted, and then tripped over to the left, and remained upturned on the flats of the two left side wheels. The chain came off the grounded rear-wheel sprocket, and the motor turned the right hand wheel rapidly in the atmosphere.

Finding nothing broken, in his own frame work, the writer stood boldly on his feet and wiped the blood off his nose. The driver of the car landed on his feet uninjured. "The steering gear is certainly too light," said the observer to the designer, as both regarded the high-wheeler lying on its side, while the broken steering-rod was visible lying on the road. When the car was righted the right rear-wheel was observed to stand about thirty degrees off perpendicular, top outward. The designer gathered up the bent and broken steering-rod, and together we pushed the car on the grass at the side of the road, where it stood with its front wheels at different angles. Fortunately, the trolley station was near a hand, and a car due in ten minutes.

Many cars are faulty in front-axle and steering linkage construction. The yoke opening is often smaller than it should be, and it seems to be almost the rule to make the steering arms too short. Their dimensions, however, showed a general increase in the 1907 models, but longer stub axle hubs and pins and longer steering arms are yet sorely needed in many cars which are otherwise fairly well proportioned. There is no valid argument against very long steering arms, and very long knuckle pins, as the strength and front wheel steadiness gained far more than offset the slightly increased weight.

In case of high-wheelers, long steering arms and long stub-axle or pivot pins are imperatively demanded, because the road-obstacle leverage increases as the wheel-diameter increases, and is also made more effective by the substitution of the solid tire, for the pneumatic.

The light weight and low speed of the high-wheeler are favorable factors in the problem, but the large wheel diameter, and the solid tires, which do not mount obstacles so readily as pneumatics, demand ample front wheel supporting and controlling element dimensions, and the increased vibration caused by solid tires calls for the best of fitting thruout the entire steering linkage.

There seems to be no good reason for the very short wheel base of such cars. The first American cars were very short in the wheel-bases, 56, 60, 68 and 72 inches being used, and as the first successful high wheeler had a short wheel-base, it undoubtedly very greatly influenced the present high-wheel practice. Increase of wheel-base adds very little to either the cost or weight, and every added wheel-base inch improves the solid tire riding perceptibly.

Doubtless there will be a great number of high-wheel cars made and used, and it would be well if they had much more wheel-base and much better built steering linkages than are now placed in many of this class of motor cars.

The Ford Motor Co., Detroit, Mich., announce that there will be no change in the 1907 six-cylinder model for the season of 1908.

During the recent visit to Boston by the Japanese General Kuroki, he was driven about in automobiles and he was so imprest with the usefulness of the automobile that he exclaimed that every modern army organization should include an automobile corps and that he would do his best to have one in the Japanese army in the near future.

Ezra E. Kirk, formerly with E. R. Thomas Motor Company, has been appointed western sales manager for the Rainier Company. He will have charge of the territory west of and including Pittsburg and Buffalo.

The organization heretofore known as the City and Country Motor Club has been superseded by a new club called the New York Automobile Club, and the new organization has taken over the entire equipment of the former, including the two club houses. It is probable that the officers of the former club will be re-elected as officers of the new club.

Trade Changes and Removals

Anderson Carriage Co., of Anderson, Ohio, has recently been incorporated as the Anderson Carriage Co., Inc., with the following officers: A. D. Anderson, president; W. R. Pervical, vice president and general manager, and E. R. Wooley, secretary and treasurer.

Buick Auto Co., of Flint, Mich., has increased its capital stock from $1,500,000 to $2,000,000.

Columbus Carriage Company, of Columbus, Ohio, carriage business sold to Ohio Carriage Mfg. Co., of Cincinnati, Ohio. Stockholders and officers will engage in the woodware business under the name of the Columbus Woodware Co.

Crescent Parts Co., formerly located with Wycoff, Church & Partridge, New York, is now situated at 244 W. Forty-ninth street.

Electric Storage Battery Co. have moved their San Francisco, Cal., offices from 11 Hawthorne street, to the Crocker Building.

Fedders Mfg. Company, Buffalo, N. Y., will shortly remove from their present location, 1592 Genesee street, to 57-59 Tonawando street.

Federal Rubber Company, Cudahy, Wis., has increased its capital stock from $100,000 to $620,000.

Gabriel Horn Mfg. Co. has removed from 3900 Hamilton avenue, to 1407 E 40th street, Cleveland, O.

General Accumulator and Battery Co., of Milwaukee, Wis., is contemplating a large increase in its capital stock.

Gemmer Engine Co., of Wabash, Ind., has been succeeded by Gemmer Manufacturing Company, of Detroit, Mich.

Hildreth Motor and Pump Co., of Lansing, Mich., style changed to The Hildreth Mfg. Co.

O'Neil, J. E., Lawrence, Mass., dealer, has incorporated his business under the style of O'Neil Automobile Garage Co., Inc.

Pope Mfg. and Construction Company, of Fond Du Lac, Wis., has filed an amendment changing the name to Pope Boat Company and increasing the capital stock to $25,000.

Pittsfield Spark Coil Co., inform us that they have removed from Pittsfield, Mass. to Dalton, Mass.

Randall-Faichney Company has removed to Sudbury Bldg., Boston, Mass.

Sport's, Ltd., dealers and agents in automobile accessories and motor cycles in New York city, have removed from 1775 Broadway near Fifty-seventh st., to 2049 Broadway, near Seventy-first street.

Wright Cooler and Hood Mfg. Co., have removed from 335 Wabash avenue, to 1545 Michigan avenue, Chicago, Ill.

Fires, Judgments and Failures

Badger Brass Mfg. Co., of Kenosha, Wis., defendant in suit by S. W. Rushmore, of Plainfield, N. J., dismissed.

Craig-Toledo Motor Company, of Toledo, Ohio, is now in the hands of a receiver, E. J. Marshall.

Duryea Power Company, of Reading, Pa., defunct, creditors voted Berks County Trust Company trustee.

Grout Automobile Company, of Orange, Mass., plant is closed at present. W. L. Grout has filed an attachment for $200,000 on the plant. It is stated that the financial standing of the company is in no way impaired.

Mott & Smith, at Central and Cleveland avenues, Far Rockaway, N. Y., was damaged by fire, caused by explosion of gasoline.

Mastin, J. H., machine shop and garage at Auburn, Neb., destroyed by fire June 27.

Osen & Hunter, San Jose, Cal., large garage, totally destroyed by fire on June 27, causing a loss of $65,000.

Smith, Fred M., bicycle dealer of Hibbling, Minn., filed petition in bankruptcy.

Treat & Clark, Bangor, Me., dealers, dissolved partnership, Clark retiring and J. H. Nash being admitted to the firm.

Western Motor Car Company's garage, Sacramento, Cal., located at 1004 K street, was destroyed by fire on June 18. Loss approximately $4000.

Willis, E. J. Co., New York city, defunct, Jesse Watson was elected trustee.

Wilmington Automobile Company of Wilmington, Del., slightly damaged by fire.

Legislation

CONNECTICUT.

The new bill as past by the Legislature provides for a maximum speed limit of 25 miles per hour everywhere in the State, whether in city or country. The law also provided that a driver's license shall be forfeited upon his third conviction for going over the 25-mile speed limit. Low powered cars are taxed $5 per year, while cars over 30 horse power are assest $10 per year. The minimum age limit of a driver is set at 18 years.

INDIANA.

Evansville—In accordance with new ordinance the speed limit is now eight miles per hour.

MASSACHUSETTS.

The new registration law which goes into effect August 1, places the annual fee at $5 for automobiles and $2 for motor cycles.

Creditable Performances

A two-cylinder Reo touring car entered in the recent Copenhagen Auto Club reliability run in Denmark on May 26, finished the 300 kilometer course with a perfect score.

National Motor Vehicle Company, of Indianapolis, Ind., still claims the world's record for 24 hours, which is 1094 3-16 miles, as this record was established by one car only.

The Pope Toledo stock touring car driven by Lytle in the twenty-four hour endurance race at Detroit, June 21-22, up until the accident, broke all world's records for endurance on circular track by forty-nine miles.

On June 24 at Bridgeport, Conn., the 24-horsepower Premier stock touring car, which was started on a non-stop engine run on June 3, under the auspices of the Bridgeport Automobile Club, completed the test, having covered in all 4906 miles.

The Fawkes Automobile Co., of Minneapolis, Minn., have just completed a 222 hr. non-stop run with a 1907 two-cylinder Rambler. The run was started on May 10, at 3 P. M., and continued until 9 o'clock Sunday evening the 19th. The car finisht in perfect condition.

The Haynes runabout which Mr. C. B. Warren drove in the sealed bonnet contest with success is still sealed, and has covered a total of nearly 1000 miles. The car will be driven in demonstrations with the seals intact until it becomes necessary to break them.

S. D. Waldon, sales manager of the Packard Motor Car Company, of Detroit, recently made a notable run from Detroit to New York City in a 1908 thirty-horse power Packard test car, with a load of four persons and heavy baggage, covering the 797 miles in two days, altho during the greatest part of the distance rain and mud were encountered.

The Mora Racytype No. 184, which was entered in and completed the 600-mile run of the New York sealed bonnet contest with a perfect score, has traveled in all 2863 miles with all seals unbroken. The car, after finishing the New York contest, journeyed to Chicago, where it entered the sealed bonnet contest of the Chicago Club. It came thru with all seals intact, but penalized a few points for being late, caused by a wagon backing into it and bending the axle. The car was then turned towards New York, where it arrived with all seals of both clubs intact.

The American Motor Car Manufacturers' Association, after a thoro discussion of the Chicago show question, have decided to work in harmony with the N. A. A. M. in the promotion of the affair in Chicago this December.

Two Locomobile Models for 1908

lready the season of 1907 has been rele-
d to the past at the great factory of the
omobile Company of America, in Bridge-
, Conn., and all hands are living and
king in 1908. In other words, the last
car rolled away to its owner long ago,
the busy shops are rapidly turning out
models, the first trial machines having
on the road under test for many months
re manufacturing was commenced. The
pany has adhered to its policy of build-
two models; these are practically identi-
in their mechanical features and general
gn, the main difference being in the mat-
of dimensions and power. The smaller
hine, designated as Type E, is rated
0 horse power, while the larger car,
e I, has a 40 horse power motor. In
cases the design is the same. Both
have 4 speed selective transmissions,
e and break ignition, double chain drive;
materials and workmanship being iden-
. Each chassis may be had as a runa-
bout, a touring car, a limousine or a la
daulet. The smaller machine, Type E, ca
be furnished with a removable tonnea
which is interchangeable with a rear dec
or boot carrying a rumble seat, which fol
down and out of sight when not in use, ar
a capacious box just behind the rumble se
in which no small amount of touring requi
ites can be stowed. The fastenings consi
of wing-nuts, so that no tools are require
for changing over from touring car to ru
about, or vice versa; two men can readi
make the change in twenty minutes. Whe
either the rear deck or the tonneau is
position there is nothing to indicate that
is not permanently attached to the car; eve
a close inspection does not betray the inte
changeability of the body. In the case of th
larger car, Type I, the same scheme may b
employed. It also has the folding rumb
seat and, naturally, more stowage spac
than the 20-horse power runabout. An alun
inum dash of the dished type is fitted to th

DOLSON

1908

IT is with that degree of pleasure which follows only the knowledge of a rare work well accomplished that the Dolson Automobile Company announces the completion of its nineteen hundred eight models and their readiness for immediate delivery to agents.

These splendid cars are the elaboration of nearly forty years of vehicle building, and nothing that human skill could devise or ingenuity suggest has been spared to make them the royalty of motordom. In beauty of design and in luxury of appointment; in that delightful silent flight which is so exhilirating to all who know it; in absolute worthiness of construction; and in all those finer concomittants that go to make automobiling the perfect pastime, the nineteen hundred eight Dolson cars measure up to that high type of motor car refinement and efficiency which has for years been the ideal of John Dolson and the chief aim of his automobile career.

Following out the well-known Dolson power policy the nineteen hundred eight models continue to be among the highest powered shaft driven cars built. They are veritable Samsons in the automobile world. The strength of giants is in their loins of steel. John Dolson has for years been a most consistent advocate of high power in automobiles, and has lived to see his theories, once rejected as extreme, approved and successfully applied by the self-same engineers who once derided them. Power is the soul of the automobile, and for years Mr. Dolson has devoted his energies and ability to the perfection of the high-powered motor car and in this nineteen hundred eight creation he has given to the public a Goliath that will plow the sands of the western deserts or mount the grades of nature's huge upheavals where lighter powered cars would choke and die of their own impotence. Power and simplicity have been the Dolson watchwords—and they make for all that is really great in the motor car.

The nineteen hundred eight models are all four-cylinder cars, and comprise the Dolson Sixty—seven passengers, the Dolson Forty, and the world-famous "Cannonball." There are no frills on the new cars. They are sane and simple in construction, and regal in their marvelous strength and surpassing beauty. Price considered, there is not on top of earth so good, so great, so worthy an automobile as

"THE CAR JOHN DOLSON BUILDS"

The Season of 1908 promises to break all records for sales of high powered cars. The manufacturing capacity of the Dolson factory has been largely increased for the coming season and we can handle several good contracts in addition to the agencies already established. Immediate deliveries can be made and early correspondence is solicited.

dauiet or limousine body.

ller car when equipt as a touring car or about, but with a limousine body a ight mahogany dash is employed. The orse power chassis always takes a ma- any dash, regardless of the style of y.

n interesting feature of the 1908 20-horse er car is that it is equipt with a four- d selective change-speed gear, similar to used on the larger car, but of smaller ensions. In the 1907 model there are three speeds, controlled by a progressive r. The four speeds make the car an emely handy one to drive, especially in a country, as it is possible to keep the ne running at the most advantageous of speed under any condition of grade oad surface, and to secure the most eco- ical operation and the greatest speed ob- able from the horse power.

he description that follows may be taken pply equally to both models, except where exceptions are specifically noted. In fact, is a difficult matter to distinguish one chass from the other except by comparison of d mensions, and this similarity extends als to the unseen parts and to the methods c construction employed thruout. The cy inders are cast in pairs, as heretofore, ar are mounted on a manganese bronze cranl case, a method of construction that has give satisfaction after several years' use. A ne feature for 1908 is the use of a bronze pla to close a large opening in the head of th water jacketing; the uptake for the wat circulation is connected thru this cove plate, the removal of which gives free a cess to the water jackets for cleaning ar inspection. Valves are all mechanically ope ated and symmetrically arranged on opposi sides, inlet valves on the right. Each can shaft is made from a single bar of steel, can integral, so that there is absolutely nothir to work loose or give trouble. The can

If the oil in lubricator becomes exhausted a fresh sup can be pumped up from the auxiliary ta This arrangement is infinitely more agr

Chassis of the 40-H. P. 1908 Locomobile. The 20-H. P. car is practically the same, except f dimensions. Power plant and radiator well back, giving good weight distribution. Wheels 36 inche rear tires, 4½ inches; front, 4 inches. Rear springs, 50 inches long and front, 40 inches. Wheel bas 123 inches.

egrally with the exhaust cams and act-, of course, on the exhaust valves. The gneto is of the low-tension type, the same used in the 1907 models, and is secured a strap-and-bolt arrangement, but bolt is now on top instead of at the side. flexible coupling has been placed on the np shaft to insure against binding and make it an easy matter to remove the np. The pump shaft carries a flanged ley for the fan belt.

Warm air for the carburetor is drawn thru holes in flanges cast on the exhaust nifold—a new feature. The air pipe ex-ds across the engine between the pairs cylinders to the carburetor on the inlet e; a valve regulates the volume of warm admitted, this valve being close to the

able than the familiar plan of carrying a of oil in the tonneau, or strapt to some p of the car. This arrangement is omit from the smaller model, which carries gallon of oil, enough for several hund miles, as the company claims a record over 500 miles on one gallon of oil for t car.

MANUFACTURING METHODS.

In the manufacture of the engine a nu ber of interesting processes are employ some of which are extremely simple, n withstanding their effectiveness. For stance, piston rings are so finished that wh placed in their cylinders they fit as clos as if they had run long enough to beco worn to an exact bearing surface. This accomplished by placing the rings after th

The 1908 MITCHELL

at all agencies

September 1, 1907

The 1908 Mitchell, the finest touring car in the world for $2000 as well as the runabout and the NEW Mitchell Roadster shown at all agencies September 1, 1907. See them. Say to any Mitchell agent—"Show Me." He'll show you in a Mitchell for 5 miles or 50 whichever you say. Convince yourself that for power, control, silence, speed and sweet running there is nothing can equal the 1908 Mitchell at the price.

The 1907 Mitchell a Winner

At Hamline Track, St. Paul, Ed Zerbies in the 24 hour race, after wrecking two cars on the fence at the turns because of the dust—having no other car, borrowed a 20 h.p. Mitchell Runabout from a doctor in the crowd and drove it for nearly four hundred miles until another Mitchell 35 h. p. could be secured. In the face of this awful handicap Zerbies finished only 28 miles behind the winner who drove a 40 h. p. car, selling for over twice as much as the Mitchell, and in addition broke all previous world's records for 24 hours—183 miles.

The 1908 Mitchell chassis is a refinement of the 1907 with all the latter's good points and the same standard construction. You can't afford to overlook the 1908 Mitchell.

908 Locomobile 40-H. P. Motor. Inlet side, show- the make and break ignition system, the band thod of holding the magneto and the special oil holding bracket.

d worked back and forth, just as is the ton in the engine, with a little abrasive ostance to remove the irregularities from rings. As a result of this process the gs are worn exactly as they would be rn by actual use in service, and when y are assembled into their engine they closely and hold compression as well as they had been run for some time. Anher result is that they remain tight for a g time. It is, of course, necessary to new the grinding cylinders at frequent ervals, as they are quite rapidly destroyed; this is found to be well worth while, in w of the good results obtained from the ocess.

After leaving the grinding machine on ich the preliminary work is done the rings magnetized, thanks to the magnetic chuck which they are held, and in this condin would be sure to attract and hold small rticles of metal. There would consequentbe unnecessary wear on the cylinder walls, ton rings and pistons, and under some cumstances this might become very seri-. A simple demagnetizing apparatus has n installed, however, and this, when ought into use, leaves the rings as free m magnetism as they were before grind-, removing the possibility of trouble from s source.

The connecting rods are of high-carbon, en hearth forged steel, the solid wrist-pin ls bushed with hardened steel and the it big ends lined with Parsons' white ss. It has been the custom at the Locobile factory, to bore out the big ends in oring machine, and then fit each one to own crank pin by scraping. While this thod was good, a better one has been lved. The bearings are bored a shade aller and a mandrel of highly polished l hardened steel, very slightly tapered l of the exact size of the crank pin at largest part, is forced thru the big ends, pecial press being used for the purpose. e passage of the mandrel expands the

tion, both for smooth running and for sisting wear than a scraped or machi bearing. Actual tests made before this p was adopted showed that bearings that w mandrel-finished wore longer and better t scraped bearings. The main bearings of crank shaft, which are also lined with P sons' white brass, will be finished in the sa way. The crankshaft is machined from solid hydraulic forging of alloy steel.

CLUTCH AND CHANGE SPEED GEAR

The clutch is a simple cone of ample dia eter and width, faced with heavy leat backed by flat springs; the springs cause clutch to take hold gradually, starting car without jerking and jumping and only making the car pleasant to ride in, also saving wear and tear on the eng and transmission mechanism. Spring thr is self-contained when the clutch is engag The universal joint between the clutch a the gear box is made up of steel forgin hardened and ground; the pins are stati ary, held in position by bolts with castella and cotter-pinned nuts, and the bearing s face extends nearly the full width of knuckle.

The gearbox is made of manganese bron with cover-plates of aluminum compositi and all the gear shafts run on Hess-Bri ball bearings. A rearward extension of main casing contains the differential and bevel gears driving the countershaft, wh also turns in ball bearings. There are t sliding groups on the squared shaft, c having two gears for first and second spe and the other a gear and a clutch for third and fourth speed respectively, the dr being direct on the high speed. On right hand side of the gear case the co tershaft carries the drum for the foot bra This drum on the 20 H. P. car is ten incl in diameter and three and a half incl wide. On the Type "I" car it is 12x4 inch The brake is operated by a foot lever, the usual way; lubrication of the large me

THE PERFECT CARBURETOR

Read These Claims and Give a Chance to Prove Them to Yo

Model D—Universal

Is the simplest, most effective curburetor e devised.

Gives a better mixture, yet a more economi mixture, than any other carburetor.

Gives the greatest mileage per gallon of fuel

Is equally effective at all altitudes and in temperatures.

Gives a perfect gas supply on the steep grades and around curves.

Has fewer parts than any other carbureto easily cleaned and easily understood by amateur.

Is equally effective on two or four cycle engi

This is precisely the sort of carburetor have been hoping would some day be made. We got it! Do you want the proof?

ar sprockets are formed integral with the eel brake drums, the whole being bolted the enlarged spokes of the rear wheels. e emergency brakes are of the internal type, d are entirely inclosed. Sizes are as fol-ws: Type "E," 11x1½ inches; type "I," x2. Steel cables form the connection be-een the lever and the brakes. The lever cillates a transverse shaft and a short arm each end of the shaft carries the front d of the cable thru which it is connected th its brake. The total braking surface of e Type "E" car is about 220, and of the ype I car about 320 square inches.

AXLES AND STEERING GEAR.

Both front and rear axles, in both cars, e of forged steel, of I-beam section, and th are dropt, the rear axle being "crank-" near its ends and the front axle having graceful downward sweep at the center. ring seats and, in the case of the front le, the steering yokes, are forged integral ith the axles, so that each is in a single lid forging. The steering yokes and piv-s, upon which so much depends, are sub-antially designed. The transverse rod con-cting the steering pivots is placed behind e axle, where it is protected from acci-ntal damage, and conforms to the sweep the axle. The joints are of the ball-and-cket type, with spring buffers to absorb ocks, and are inclosed in leather boots, hich exclude dust and dirt and retain lu-icating grease. The steering gear is of e worm and sector type, both worm and ctor being glass hard, and by means of an centric bushing on the sector shaft wear n be taken up, obviating any back lash hich may develop after long use. Spark d throttle levers are mounted on top of e steering wheel, but do not move with e wheel. Their movement is carried thru e steering tube by means of smaller con-ntric tubes carrying at their lower end nall bevel gears meshing with similar ars on the lower ends of short vertical afts whose upper ends carry the levers ru which the throttle and spark are con-olled. The hand wheel is of bronze with a n or grip of black vulcanized hard rub-r moulded over the bronze, making a ndsome, durable and comfortable rim to e.

The frame is of prest alloy steel thruout. d the cross members to which the trans-ission is hung are deep and substantial. he rear ends of the main frames are con-ected by a steel bar passing thru holes the end forgings; the outer ends of these rs carry the spring shackles. At the front d of the frame is a dropt member or

so that the front of the radiator is a behind the center line of the front axle. results in a good distribution of the wei makes the car handle well and adds no little to the comfort of the passengers. Se elliptic springs are employed thruout.

WHEELS AND TIRES.

On the large car, Type I, the wheels thirty-six inches in diameter, front and re the rear tires are four and a half inch the front tires four inch. The rear spri are fifty inches long and the front spri forty inches. On the smaller car, Type the wheels are thirty-two iches in diame front and rear, and both front and rear t are four inch. Rear springs are forty-f inches long and front springs thirty inches. The wheel bases are a hundred twenty-three inches and a hundred and inches respectively for touring cars. W Type E is built as a limousine, howe the wheel base is increased to a hund and sixteen inches, fourteen inches lon than the touring car. All wheels run ball bearings.

FORGING AND HEAT TREATMENTS.

All drop forgings used in the Locomol approximately 200 together with the d dies, are made in the company's own fo ing plant, which is in itself a manufactu plant of no small magnitude. After fo

1908 Locomobile, showing the rear of the dash the control levers and pedals. Practically no cha have been made in the control of the large car a 4-speed selective system of change speed si to the large car has been installed in the 20-H model.

ing, the parts are subjected to delicate h treating processes by which the strengt enormously increased and each is given proper hardness for the work it is to Some parts, such as gears, are given a f heat treatment after being finished, as

Are You Prepared for the Worst Roads?

Not all motoring is over good roads. If it was, most any tire would do. If we could eliminate the unlooked-for tests that are given to tires on next-to-impassable roads—roads that have to be covered in cross-country runs—it would not be necessary for us to insist on so much extra strength in

MORGAN & WRIGHT TIRES

There is absolutely no "theory" about this extra strength matter. Any motorist who has traveled off the city boulevards knows that it takes a wholly different tire to stand up on all sorts of roads than it takes to travel around town. And for this reason, the Motorist who is planning a tour had better fortify himself with all the extra tire strength he can buy.

We wouldn't talk so loud about this matter if our tires hadn't proven their value so frequently under trying road conditions—if it were not for the extra strength that is put into them for use on the worst roads.

WE MANUFACTURE A FULL LINE OF BATTERY JARS AND ACCESSORIES OF A 1 QUALITY. SEND SPECIFICATIONS AND GET OUR QUOTATIONS

itude of the plant involved in the making nd heat-treatment of forgings can be ıdged from the fact that the consumption f oil for fuel amounts to a thousand gal-ons a day. All forgings are pickled in acid, nd subjected to a sand blast and then hand led.

All finished parts are sent to a testing de-artment before being assembled, and are ubjected to minute tests for accuracy, ver-ier instruments and micrometers being em-loyed, together with special testing ma-hines for special parts. Errors of more han a thousandth part of an inch result in he part being sent back to be made right; r, if the error cannot be corrected, the part "scrapt." One of the most intricate ieces of work in the whole establishment is he cutting of the camshaft for the inlet de, with its eight cams—four for the valves nd four for the ignitors—the latter with heir varying contour. A special machine or this work was designed and built at the ocomobile factory, and is almost human in s weirdly automatic action.

special enamel which makes a perma foundation for the finishing coats of p and varnish. The color put on the ca the paint shop is optional with the purcha

In outward appearance, generally speak the 1908 Locomobile cars resemble models, altho the Type "E" car is so what altered. There are no swee changes in either model, the most impor departure from 1907 design being the stitution of a four-speed selective gea Type E for the three-speed progressive used in the 1907 car and a much larger gine in the large car. The sprocket bo forming steps leading into the tonneau, been worked out a little differently a outward form, looking neater and at same time occupying less space. Square lamps will be standard equipment ins of round ones. Another detail is a new rail which, when not in use disappear the top of the front seats. The equipm includes five lamps, generator, horn, to spare parts, top irons, tire carriers and rest.

The 1908 "Griswold" Cars

HUGH DOLNAR.

The Griswold Motor Car Company, De-roit, Michigan, U. S. A., placed the first ne of its cars on the road early in May, 907. This car is unique in having a vertical notor crank-shaft and a symmetrical fric-on drive, and is here illustrated and de-cribed in some detail for the first time in ny publication.

The Griswold cars are built from des by Mr. Joseph P. La Vigne, widely kn as a machine-tool designer and builder to the motor car trade as the inventor patentee of the La Vigne oiler.

He had his first motor car on the roa New Haven, Conn., in 1899. The wheel of this car was 65 ins., gage 56 ins.,

Ballinger & Perrot

2. Right side of Griswold motor. The bevel and pinion at the top are for starting, the hand- being applied to the left end of the horizontal g shaft, at the rear of the foot-board. The stands on top of everything, in the middle of iassis frame, whence it can be removed without bing the transmission. By removing the crank- nd-covers the crank-shaft and rod-ends are fully ed to the eye and hand from both sides, making x adjustment very easy indeed. The water cir- on is thermal. A 5-lead oiler is fitted, but only ds are used. The ignition is jump-spark, with oils in a coil box inside the front board, and dry in a compartment under the driver's seat. The ank, 10 gallons capacity, 100 miles range, is also d under the front seat. The fly-wheel is cased the sides, so as to be safe when running.

ins. front and 42x4 ins. rear. The mo- vas 3, water-cooled, 4x4 ins., 2-cycle cyl- rs, crank-box pressure cylinder-supply. transmission was two speeds forward pur gears, internal friction-clutch-selec- all gears always engaged, with spiral to the divided rear axles. The reverse by reversing the motor. This car had nabout body to seat two passengers, lever steering, weighed about 1800 lbs., could make 45 miles on a level road.

is car was burned up from a gasoline three months after it was first placed he road, and as La Vigne was busy manufacturing automatic screw ma- es, he did not place another car on the until August, 1901. This second La e car had 110 ins. wheel base, 55 ins. , all tires 36x3½ ins., motor, 3 cylin- 4½x4½, water-cooled, 2-cycle and re- ng, same general transmission scheme first car, with spiral gear to the divided axles. In his first car, La Vigne placed motor crosswise, under the car-body: second car motor was placed under a in front. This second car weighed t 2300 lbs., and could make 55 miles, vas never fully completed as capital was to take up the 2-cycle motor.

r. La Vigne's next attempt was known La Petite," wheel-base 60 ins., gage s., tires all 28x2½ ins., motor two, air- ed, 4-cycle, 3x3 in. cylinders, set at 30- apart, both connected to one crank, ders under the hood in front, still the two-speeds forward drive, friction se- on, but with a reversing gear and bevel-

only arrangement which gives a symmetri- cal construction with the friction disk an traversing-wheel speed-change and reverse This "Griswold" model, the first of a pro jected line of light, moderately-priced car is here shown as a 3-passenger runabou driven by an opposed pair of horizontal cy inders, set lengthwise of the car under th middle of the hood, with a vertical crank shaft, and an aluminum alloy friction dis on the under side of the horizontal fly-whee This vertical placing of the crank-shaft per mits locating the traversing friction whe in the middle, under the fly-wheel, so tha the line shaft can be placed in the middle o the chassis frame, with bevel gear to the di vided rear axles, thus obtaining a symmet rical friction drive.

At first thought the vertical crank-shaf seems an awkward arrangement, but com prehensive consideration shows it to be ad vantageous at every point, and to reall eliminate the fly-wheel load which is car ried by the horizontal crank-shaft with th friction speed change and reverse, as wi be shown in the detailed description.

NOTABLE FEATURES.

The objects sought in this design wer lengthwise placing of the opposed moto to avoid vibration, the location of the mo tive and speed change unit assemblage un der the hood in front, where everything i accessible, and the obtaining of a symmet rical friction speed change and reverse. Pre vious practice placed the opposed cylinde motor crosswise, which necessitates shor stroke and short connecting rods

La Vigne, by using a vertical crank-shaf was enabled to use long cylinders and rod lengthwise of the car, largely eliminating vi bration, and bringing the aluminum drivin disk fixt to the horizontal fly-wheel in th middle of the chassis frame over the frictio

The 1908 Buffalo Carburetor

A mechanical carburetor in all that the term implies. Its movements are not left to chance, but it is positive in its action throughout its entire range, from zero to full opening. Atmospheric conditions do not alter its perfect working. Its construction throughout is based on the correct principles of carburetion.

The entering column of air passes the gasoline nozzle at adjustable openings in the cone valve. The cone valve and the throttle are link connected and move in unison. Both are adjusted to give the proper mixture for slow speed. As increased power or speed is desired, the cone valve and throttle are rotated by the operator, increasing the quantity of mixture admitted, while the speed of the mixture passing the nozzles is kept the same. This feature insures a perfect mixture for all powers, prevents a greater quantity of fuel from being drawn by the motor than can be properly burned and accounts for the great economy obtained with a 1908 BUFFALO MECHANICAL CARBURETOR.

Skilled workmanship and high-grade materials only, enter into its construction. The leading American Motorcars, such as Ford, Corbin, Welch, Knox, Wayne, Jackson, Queen, Wolfe, etc, use the **Buffalo.** It was the equipment of the Ford car which broke the world's record in the recent 24-hour race at Detroit. If **you** try the 1908 "Buffalo" you will be convinced.

BUFFALO CARBURETOR CO.

u the front-board, and having a ratchet the rear end to which the hand starting-nk is applied.

'he crank-shaft, crank arms and crank have a continuous oil hole beginning the top and ending at the middle of the er crank-pin. This oil hole takes a heavy ase cup at the top which would supply lted grease if sufficiently warmed; cross-e oil-holes thru the crank-pins oil the necting rod wrist-bearings from a force-d oil-lead which supplies the crank-shaft hole in the middle of the top bearing

and one in front, pedal controlled, lift friction-wheel casing and wheel-shaft jo nals vertically to press the wheel against t driving disk. The pedal-thrust is tra ferred to the three wheel-lifting eccentr thru a single coiled spring which gives sistance enough to something more th lift the weight of the fly-wheel and cra shaft, but is not so stiff as to permit jurious lifting power to be applied to t friction wheel.

The arrangement of parts described giv the longest possible line-shaft for a giv

Fig. 4. Under side of Griswold car, showing the friction-wheel, standing about the middle of its minum casing, which is cut away in this first car to expose the friction-wheel, which is faced with ather fiber." The friction is of the usual form, a ring, with beveled edges, held on a metal cylinder ween metal flanges, secured with thru bolts. Thediameter of the aluminum disk, bolted to the under e of the fly-wheel is 32 ins. The traversing friction wheel is 17 ins. out. dia. x 1¼ ins. working face e leather-fiber ring is 2 inches deep, up and down, 1½ ins. thick between the flanges, and is beveled ¼ each side of the working face. The friction-wheel shaft is in Hyatt roller bearings in the casing hubs e wheel casing is cast in two parts, divided in the horizontal axial plane, so that by removing the der part the friction-wheel shaft and bearings can be released. This casing is lifted bodily towards the wheel by 3 eccentrics journaled in hangers dropt down from the chassis frame cross-girts; of these entrics, one is applied at each side of the casing in the rear, and one in the middle in the front that the casing is suspended at 3 points all in the same horizontal plane. The transfer of motion m the vertical hand-lever to the horizontal bell-crank for traversing the friction-wheel is made by ks threaded into the lever and bell-crank ends, and a flat link is jointed in the forks, which turn the screw-threads thus giving a universal action. The friction-wheel has a grooved hub to take the t-oiling shifting-rod fork. The bevel gear reduction at the rear axle is 4 to 1.

n one oil-lead of a La Vigne oiler. The er part of the crank-box holds a ring ool in which an inclined scoop fixt to under side of the under crank-arm trav-and throws the oil drippings, collected he pool, upward into the path of the ks, which beat it into mist that perfect-ils the pistons. The lower crank-shaft nal is oiled by a cross-hole from the top

wheel base, and also avoids all needle driving-shaft angle, all with suitable a convenient dimensions and 11 ins. ro clearance of the friction wheel, which more than the rear-axle bevel-gear housi has.

CONTROL.

The speed and direction changes are e fected by one pedal and one vertical han

. 5. Griswold car control. The single vertical shown in Fig. 1 gives all speeds forward and vard, and is not latched, but is retained in posi- by a leather friction disk, friction screw-adjusted, e enlarged hub of the lever. The spark and le levers are on top of the steering wheel. The ng action is the Warner worm and worm-gear . The muffler is opened by the small horizontal at the left. The pedal at the right applies the ub drum, internal brake-shoes. The middle pedal by heel and toe action to latch and release and or lifts the friction-wheel casing to release the on-wheel contact with the disk or to establish riction contact. The control is of the simplest ption, and can be learned in a few minutes. The ng-crank is applied to the sleeve and starting- shaft, seen at left of the coil box. The start- ank is seen lying on the foot-board. The starting shaft and pinion slide to the rear, drawing the ng-pinion and starting-gear out of engagement each other, so that the starting-pinion stands when not in use.

el journal seats and casing are integral, the whole casing, slotted at the top to permit the top of the friction wheel each the aluminum disk, is lifted or t bodily by rocking the specified e lifting eccentrics. The lifting pedal is ed and unlatched by a heel and toe ement so that the friction-wheel can be l or dropt instantly, and the eccen- action is powerful enough to make this l very easily moved, so that coasting ntages can be taken on all inclines e the car will run itself. The speed and tion change is extremely simple and ry quickly made, giving an ideal con- for crowded streets.

e reverse can be applied at any time, the reverse and pedal-brake together stop the car, it is claimed, in something two car lengths from 20 miles an hour.

FRICTION LOSSES.

e friction speed and direction car-con- s very cheap, is perfectly silent, can be ntly changed by an inexperienced driv- d cannot be injured by mishandling.

is car weighs with two passengers t 2500 lbs., and a pair of 5x5, 4-cycle lers can drive it over 40 miles per hour. would be very good work indeed for same motor with a geared speed- ge and shows in the most conclusive ner possible that the friction-drive is

leaves, and the rear springs are 42 ins. long 5 leaves.

The chassis frame is prest steel, 5-3 thick, 34½ ins. wide in the rear and 32 in wide in front. The greatest frame-sid depth is 4 inches.

THE MOTOR.

This motor is an ordinary commercial de sign, with special lugs to stand on front an rear inclined pedestals bolted to the chassi frame cross-girts. Both the crank-box end are applied, so that when the supply pipe i removed the crank-box ends can be take off and give a clear way from either sid thru the crank-box, making the connectin rods completely and readily accessible. Th entire motor can be removed without dis turbing any part of the transmission. Th motor shown weighs 360 lbs.

The water circulation is thermal, and th lubrication is by a 5-lead La Vigne oiler, bu only 3 leads are used.

BRAKES.

These are internal expanding in the 1 ins. dia. rear hub drums, shoes faced wit Gandy belting and pedal-applied thru a equalizer.

ON THE ROAD.

Some short runs in the streets of Detro showed the control of the "Griswold" t be extremely convenient, a touch of th foot releasing the friction pedal so that th car is made free for coasting. The 3-eccen tric linkage in this car to engage and dis engage the friction wheel and disk, gives a excellent quick, powerful and certain actua tion, so that the driver can have perfec confidence in his control, and the frictio pedal moves so easily that advantage is sur to be taken of every opportunity for coast ing.

A hundred-mile, measured-fuel run wa planned, but the car had an unreliabl speedometer and recorder, so poor as to b no use at all, and no decisive road-tes could be made. Saturday afternoon, Jul 6, the Griswold was driven with 3 passen gers over the Grosse Pointe Riverside roa to Mt. Clemens and back to Detroit, th whole run, including something like te miles of street and Boulevard work, cover ing about 50 miles. The car is very heavy much more so than will be the regular mod els, and weighed with 3 passengers up an tank and tool-box filled 2670 lbs., and th motor showed an uneven action all the wa to Mt. Clemens, not giving more than 3 miles anywhere, and sometimes almost stop ping. There was the usual uncertainty a to cause, the batteries, coil-box and car

Valveless 2-Cycle

As Usual— Something Unusual

Only 3 seconds variation per mile in a race of 50 miles.

"What!" you ll say, "only 3 seconds in 50 miles?" Yes indeed—and better than that—the two-cycle **Elmore** won the event hands down, beating a number of cars of much greater horse-power.

Yes indeed—and better than this, the **Elmore** jumped right from this first fifty-mile race into another five-mile race with a 50-60 H. P. car and won the second, hands down.

Yes indeed—and better than **ALL** this too—the victorious **Elmore** was just a demonstrating car which had just passed through one of the most trying trips imaginable over the worst roads and fords of California. All this, mind you, without a stop for overhauling or a halt for breath.

It's the evenness of the performance, of course, that's remarkable—and directly due, of course, to the valveless two-cycle construction and its resultant continuous flow of power.

Our interesting literature, called "Our Daily Mail," will furnish you with further facts.

Will you write for it.

CHAS. E. DURYEA

GRADUATIONS ON GRADOMETERS.

Will you kindly advise me at your earliest convenience what the graduation on a gradometer represents? The one I have is graduated to 30 per cent. What does 30 per cent. stand for, or, rather, 30 per cent. of what?—T. J. MENTEN.

The usual graduation on a gradometer is in "per cents." as you have stated. This means parts of a hundred and 5 per cent. grade is one which rises 5 feet in 100 feet distance; 30 per cent. is a hill which rises 30 feet in a horizontal distance of 100 feet. The road surface of such a hill is longer than 100 feet, for it is the hypothenuse of the triangle having a base of 100 feet and an altitude of 30 feet.—C. E D.

IGNITION OR CARBURETOR TROUBLE?

Sharon, Pa.

I own a 2-cylinder, 22 H. P. Buick, which is giving me a lot of trouble, principally with the ignition. One day the rear cylinder will refuse to ignite. Then when I get it to working, the front one will refuse to work. I have tried the spark on each and they seem perfect.

Then I find I have numerous explosions in the carburetor, flame immediately shoots out of the air intake pipe nearly 4 inches in length when the motor slows down. Any advice will be gladly accepted.—C. G. MOORE.

Make sure that your compressions are good and your valve actions properly right and positive. A sticking valve might cause your trouble. The probability, however, is that your carburetor is at fault. With a good gaseous mixture even a weak spark will fire, but if the mixture contains large drops of liquid these will continue to burn until the next charge is coming in, when they will ignite this charge and it explodes in the inlet pipe. This of course interferes with the next charge in the other cylinder, and destroys the power. Probably heating the air supply or heating the carburetor or heating the pipe between the carburetor and the engine will vaporize the liquid and make a mixture sufficiently quick to avoid back firing. The tendency of oil dealers is to supply a lower grade fuel than in the past and this is making the labor of the carburetor much more difficult. Carburetors have never been very perfect and the low grade fuel is decidedly demanding something better than at present on the market. A carburetor should have an air adjustment so arranged that the vacuum in the suction pipe is practically constant and the same at low speeds as at high. This relieves the variations in pressure on the gasoline supply now commonly found. Next, the gasoline should be adjustable at both extremes and should vary automatically between these points as the speed of the engine varies. The average carburetor has a gasoline adjustment for one speed only and attempts to secure results at other speeds by adjusting the amount of air admitted which is a sort of adjustment of the amount of vacuum. This method seems entirely too inadequate. I have built carburetors that meet these requirements and will describe same in the near future.

If the flame from the intake opening is light yellow the trouble may be caused also by too weak a mixture, which is also very slow burning. This may be due to carburetor adjustments, but if, after going over the ignition system particularly, the vibrator points on the coil the trouble still continues, look for leaks in the inlet pipes, as this will cause the same trouble.—C. E. D.

BALANCING ALTERED 4-THROW CRANK SHAFT.

Bridgeport, Conn., June 3, 1907.

I have a two-cylinder, four-cycle locomobile auto. five-inch stroke, four-inch bore. I have had a new shaft made, with both cranks on the same side. Originally they were opposite.

My trouble is to get the counter balance right. I first put on a weight of 15 pounds, but this seemed to be too heavy, and then gradually cut this weight down, to about two pounds. At this weight the engine runs the smoothest, but there is still too much vibration to suit me.

What I would like to know is, how much weight I should use, and how far it should be placed from centre of shaft?

The reason I placed the weight on the fly wheel is because there is not room enough to fasten it to the shaft. The distance from centre of shaft to inside of arm of fly wheel is 7 inches. The weight is placed close to rim.

H. C. SHERWOOD

You have in effect converted your engine into a single cylinder so far as balancing the moving parts is concerned. It cannot be perfectly balanced. The necessary weight is less as the distance from shaft is greater and you have probably done the best possible. If you balance the pistons a violent crosswise vibration is caused by the heavy weight, so the light weight is best even tho it does not properly balance the pistons.

A two-cylinder opposed engine with opposed cranks is capable of almost perfect balance. If twin cylinders are used the explosions do not balance. Because of these facts the single cylinder is little used and preference given to 2-cylinder opposed, triple and quadruple cylinders. C. E. D.

VARIOUS INTERESTING QUERIES.

Providence, R. I., June 10, 1907.

Will you please tell me if a rich mixture is better for pulling at slow speeds than a perfect one would be? Is it the amperage or voltage or both that increases when a set of dry batteries are connected in series, and is the power doubled when two sets are connected in multiple? What would make a two-cylinder opposed engine run backward five or six revolutions after the switch had been turned off? Does an alcohol carburetor require more or less air than a gasoline carburetor and does it require more heat? Why is a vibrating induction coil for a jump spark better than a non-vibrating coil? SUBSCRIBER.

The strongest fire is not when the stove is choked with fuel nor when it is starved, but when it has all the fuel the air it gets will burn; so a gas engine is strongest when its mixture is full rich, but not over rich or fat. If your carburetor has an adjustment which you can vary as you drive as all carburetors should you will find the point of greatest power easily. You will also find that a little reduction in power will follow a considerable reduction in the amount of fuel, but that by using a mixture less fat than that required for maximum power you will save fuel, avoid odor and soot and get better results. I think this is true at all speeds, but your carburetor may not give the same mixture at differing speeds so you may not be getting the mixture you think. More cells in a series increases the voltage proportionately and this increased o. m. f. or pressure will force some increased amperage or quantity of current thru the resistance. Connecting two batteries in multiple doubles the amperage, but does not change the voltage. Battery makers and auto users have tried to get along with few cells with the result that they have been short lived. Thus four cells will give six volts and make a good spark drawing one ampere of current or ¼ ampere each. With a proper coil 8 cells will give 12 volts and need only draw ½ ampere total or ⅛ ampere each and yet the coil gets the same number of watts (6). A cell cannot give more electricity than there is in it and will last more than twice as long if ⅛ ampere is drawn than if ¼ ampere. Further, a cell unable to give ¼ ampere still has quite some life at a lower output so that a larger number of cells is much more economical, provided the coil is wound for them. To increase the voltage above that intended for the coil is wasteful of current. When cells are new, less than the specified number can be used. A hot engine will ignite spontaneously by the heat and compression and reverse itself. Cut off the fuel first and it will not do this.

Alcohol is harder to spray so the air openings should be smaller. More gallons are used in a given distance so less air is used. More heat helps the spraying and vaporization. A vibrating coil saves current, for it will not remain on a short circuit, but buzzes. Some makers prefer the other coil. C. E. D.

MAKING A 1¾X2-INCH 4-CYLINDER MOTOR.

1107 Scott st., Baltimore, May 11, 1907.

Have read a great deal about gasoline engines in your Mechanical and Technical Department, and am in the auto shop myself, but have never read anything of an engine air-cooled with 4-cylinders, 1¾-inch bore x 2-inch stroke, which I contemplate making. I wish to have a little advice on this matter. What size valves both inlet and exhaust would you recommend, the former to be automatic? What weight of flywheel would you recommend, the size of rim, and the diameter of wheel? About what compression? I wish to get about 1000 to 1200 revolutions, as I intend it to be for cycle purposes. I wanted to bring the weight between 20 and 30 pounds. The weight of four cylinders rough is 8 pounds. Any additional advice that you can give me will be greatly appreciated by an old reader. F. W. GROSCHE.

The motor you propose is so small that the heat loss to the walls will be large and the power small. Still if it is carefully made and friction avoided in the bearings and pistons, it may be made to give you good service. Suction inlets will serve. Make the fly-wheel as large as you have room since the larger it is the lighter it may be. I would use a pretty high compression with compression space ¼ of the total cylinder contents. I think a 10-pound fly-wheel should serve. C. E. D.

PROPER COMPRESSION FOR AIR-COOLED ENGINE.

Auburn, Maine, June 17, 1907.

I am building a 6-cylinder, air-cooled engine, 4¼-inch bore, 4-inch stroke, and want a compression of approximately 60 pounds. Will you kindly tell me thru the information columns in your magazine how much space I would need between the piston and the cylinder head to obtain this compression, not taking any account of the cubic contents of the valve chambers. Is 60 pounds about the right compression for an air-cooled motor? A. H. STEVENS.

I think 60 pounds high compression for an air-cooler; air comprest to 60 pounds without loss of heat has a volume of 30 per cent. of the original volume. Therefore, let the piston movement be seven parts and the compression space. 1-7 of 4-inches equals 1-7x3 equals 1 5-7 inches for length of compression space. C. E. D.

Steam Vehicles

J. A. KINGMAN

STEAM PLANT FOR MAIL ROUTE AUTO.

Box 762, San Angelo, Texas, June 12, 1907.

The writer operates a 70-mile mail route, used four different autos on same and am now driving a four-wheel drive steamer for hauling purposes, speed eight to ten miles per hour. Kindly advise me as to best and most reliable steam outfit people. Have car nearly ready for power plant and tho I have quotations, etc., am in a quandry. Will you answer this question, please: Would a 25-H. P. August Ofeldt Boiler and a 3-cylinder 20-H. P. Dieter steam engine be a reasonably efficient and reliable plant? Does Homan's book on autos treat steam also? Am experienced with gas and only slightly with steam.

Will you kindly advise me on a steam plant maker, etc? I expect to build other machines if this proves successful, as I must have reliable hauling machines to supplement my horse service and am and have been trying to solve the overland transportation problem. Had reasonable success only so far. E. R. AMES.

Cannot give you any information about the engine to which you refer. The boiler would undoubtedly be a thoroly practical article, as the builder has had long experience with this form of apparatus for automobile work. Theoretically speaking, there is no such thing as the horse power of any boiler, so that not knowing the weight of your vehicle, the dimensions of the motor and the heating surfaces of the boiler, it is not possible to give definite information.

The book you mention refers to steam cars to some extent, but being a general work rather than a technical treatise would probably not help you very much.

In building your car you would probably not be able to get any apparatus from regular manufacturers of steam cars, but it would do no harm to drop them a line, giving them the weight of your car, speed at which you intend to run it, and ask them if their apparatus would be suitable and if they would care to sell it. J. A. K.

HARTFORD MIDGLEY TREAD TIRE
Clincher or Dunlop

Successful, Safe, Sound and Sightly

¶ From these pictures you'll get a good idea of the tires that has created a veritable sensation in all Motordom.

¶ Eminent experts like Hiram Percy Maxim, Henry Souther, Herbert Lyttle, Owners who drive, Drivers of Track, Road and Endurance Contests, Chauffeurs—all agree that it's the greatest tire invention of the age.

¶ Think what it means to buy a tire—a tire mind you—not a separate device—that will never slip or skid, even on ice. Think of 200 little spikes—like cat's claws, in each tire—that grip the ground continuously, yet that detract not one whit from fastness or resiliency.

¶ Why be satisfied with any other tire equipment? Act now. Insure the safety of your car and its occupants by putting on Hartford Midgley Tread Clincher or Dunlop Tires. Better have MIDGLEY UNIVERSAL RIMS, too. You can then use Clincher or Dunlop Tires at your option.

Millimeter Sizes for Foreign Cars

2 Cycle Engines

DOUBLE ACTING 2-CYCLE CYLINDER.

For the last few months I have read your articles on 2-cycle construction in the "Journal" with interest. I have finally got the craze myself. I have a pretty good lathe and am going to get some castings and finish them. This rough sketch will show you my idea of a two-cycle engine. I have the centers of inlet and exhaust valves directly opposite, but the exhaust has a lead of ¼-inch and opens at widest ¾-inch and ½-inch for inlet. These ports will each extend half around the cylinder. As you see I intend to have the cylinder closed at both ends and use piston with outside driving shaft to fly-

wheel. I want to use Schebler carburetor and Kingston muffler. Will one muffler work it without back charging? What size carburetor and muffler are required? I am going to try to cool with air. Can I get a magneto to work it and will it work without coil or timer? Will two small sight feed oil cups give lubrication enough.

JOHN W. JOLY.

You will find that your double-acting 2-cycle cylinder will be hard to cool, and you will have to do something new in the way of packing your piston rod, to make it stand the heat. Remember that the inside of a gas engine cylinder is full of flame during the working stroke.

You do not say how you are to obtain your charging pressure. You can fire the charge with a magneto, coil and commutator, or with magneto and hammer spark. The sellers of carbureter and muffler will tell you about sizes.

Think your scheme over carefully before you go to work on your motor.

HUGH DOLNAR.

TWO-CYCLE MOTOR IMPROVEMENTS.

7 Seminary St., Danville, Ill., May 19, 1907.

Mr. C. E. Duryea:

In looking over the C. & A. Journal I noticed your name as authority on gasoline engines and also as M. E. in connection with an association of auto manufacturers, which I thought would place you in a position to render me some assistance in having some concern interest themselves in a type of gasoline engine I have invented. I have never built one for the reason that I have never been in a position to do so, but have built many engines on the lines of the piston construction to be operated by either air or steam, which operated successfully.

My business has been as a mechanical draftsman, and have had considerable experience in gasoline engine practice, which leads me to believe that an engine built on lines of blue print is particularly applicable for auto use, altho the print illustrates a stationary type.

The data on print taken with the short description of the cycle of operation, will enable you to see that a two-cycle with one cylinder will have the efficiency of two cylinders of the four-cycle, as a positive and predetermined charge is delivered to the explosion chamber above the hollow piston at each stroke, this is attained by the use of an induction valve in the lower cylinder head, thru which a charge is drawn on the upstroke into the interior of the hollow piston, then comprest within the same on the downstroke, and delivered into the explosion chamber thru the induction valve in the top of the piston head when the latter regulates with the exhaust port for release of the average charge. The gas on the inside of the hollow piston head will be under high pressure and will enter the explosion chamber quick behind the burnt charge or up thru the center as indicated by arrows. CHARLES PICKLES.

The best way to help you is to get your device before the public in the hope that the people who are looking for a device like yours will see it and get in touch with you. The type of engine you show is not strictly new, altho I have never seen it in just this form before. It is well-known that most engines do not get full charges in high speeds, and this your device is well arranged to do. It also permits having exhaust ports all the way round the cylinder instead of at one side as is customary. It is somewhat more complicated than the usual two-cycle, but advantages cannot usually be obtained without some cost. The interior cylinder being smaller than the working one, does not permit so large a charge being introduced, but the positive introduction of the charge at high speeds will more than compensate for this. It certainly shows much ingenuity. C. E. D.

WANTS 2-CYCLE MOTOR FOR AUTOMOBILE.

Selma, Alabama.

I have been very much interested in the development of the 2-cycle engine and will be glad if there is a prospect of a motor of that type being marketed at any time at all soon. I have an old machine in which I wish to put a new motor and would like to use a 2-cycle if possible, but do not find anything in the market that looks like any improvement in the 4-cycle. Further than this the manufacturers seem unwilling to give any definite information as to the details of their designs and I do not care to purchase without at least seeing the design, as glittering generalities in catalogs count for little.

R. S. ELLIS.

I know of no 2-cycle motor on the market that is the right shape to go in a car without a good deal of trouble.

The Atlas Motor Co., Springfield, Mass., make a motor which might do you, if they would sell you a motor only.

The Reliance Motor Co., Detroit, Mich., could supply you a larger motor than the Atlas, if they would.

The Okey Motor Co., Columbus, Ohio, are making a fine 3-cylinder, 2-cycle motor, but probably would not sell a motor only, as they have only a small place and are building a first lot of cars.

You might write to the Du Brie Motor Co., Detroit. Without doubt the 2-cycle motor can drive a car. H. D.

QUESTION OF HEATING UP OF 2-CYCLE, DOUBLE-ACTING MOTOR.

Webster Groves, Mo.

Will you kindly answer the following questions in the next number of the Journal? Would a double-acting, 2-cycle, get too hot to run? I mean a gasoline motor with an explosion on each side of the piston every time the flywheel turns, same as a steam engine. I have a design for such a motor. This motor has large exhaust port openings, which I think would help a great deal towards keeping it cool, and there is the two charges of fresh gas to help the cooling also. WM. F. SCHOENHARD, JR.

Write to De La Vergue Co., Port Morris, New York, for a circular or catalog of double-acting, 2-cycle engines. Double-acting, 2-cycle motors, water-cooled, are now the leading European prime mover, and are made in very large sizes, up to 8000 H. P. or more. Do not throw away money on experiments until you inform yourself as to what has been done. You cannot, probably, make a small double-acting, 2-cycle motor that will run well, without more knowledge of the art than can be given you in this place.

H. D.

TESTING 2-CYCLE COMPRESSION BY THE GAGE.

I want some information regarding a 2-cycle engine which I have in an automobile.

First of all the compression registered by a steam gage while cranking engine as you do when starting engine is 85 lbs.; then while having gage on one cylinder and running the other by its power, the pounds register on the gage are 125 lbs.; understand there is no explosion in cylinder upon which gage is fastened.

What I would like to know is the number of pounds the gage should show when applied as stated above, that is the number of pounds when cranking and number of pounds when running the other cylinder by power; also compression space in inches, cylinders having no pockets.

The sizes of the cylinders are 4½-in. dia. x 6-in. stroke, and they develop 12 brake horse power.

The explosion in the cylinders judging from the action of the engine must be very violent.

What pressure will there be in the cylinder at the time of explosion with the compression I have; also what pressure when exploding with proper amount of compression?

Had the exhaust of the engine ought to be heard in the exhaust pipe? J. W. O.

With a good muffler there should be no noise in the exhaust pipe. With no muffler there will be plenty of noise.

Your cylinders are probably packed with snap rings, ordinary pattern, with cuts right thru them, which are next to no use at all when the piston moves slowly. The holes thru the rings are not very big and when the piston moves fast the air cannot escape as rapidly. Ninety lbs. is about as much as your gage should show, and is much higher than usual in 2-cycle engines. Pack your pistons with ordinary, 3-ring, steam-engine piston rings, so they will be tight, and the gage will show the same whether you crank the motor fast or slow. At speed the hand will jump, its highest reading is not correct.

For 6-inch stroke from inside edge of exhaust port, cylinder bore all one diameter to the head, a cylinder about 6¾ ins. long, not deducting any space for the exhaust port, should give you 90 lbs. compression when you have tight pistons. The working pressure is supposed to be 3 or 4¼ times the compression. Your pistons are 6-in. stroke—you do not give the exhaust port length so your question cannot be definitely answered. H. D.

BENT RADIUS ROD DUE TO BRAKING.

New York City.

As a subscriber and reader of your Journal for the past three years, I desire to ask your expert opinion on the following:

I have a 30-60 H. P. car of American make, chain driven, and yesterday was informed by the garage that the right radius rod, running from the sprocket to the rear wheel, was so bent at the double-threaded extension joint as to necessitate the same being reforged and rethreaded. On examination I find the rod bent up nearly three inches. The explanation offered was that in backing the car at some time the brakes had been put on too suddenly and thus the weight of the car and its momentum had fallen on the radius rod and caused it to buckle. On my inquiry why braking the car when it was running forward did not have the same effect, I was informed that when the car runs forward and brakes are applied, the radius rods are under a pull (or tension) and hence kept straight, but when the car runs backward and brakes are applied, the radius rods are under a push (or compression) and hence would buckle. This explanation does not seem reasonable to me. The radius rods are always under both a pull (or tension) and a push (or compression) at the same time, and whether the car is running forward or backward makes no difference on application of the brakes. The function of the radius rods is to overcome any variation of the distance between the driving sprocket and the rear axle, which might be caused by the up-and-down motion of the rear springs, or possibly by the tightening or slackening of the chains. The running of the chain, either backward or forward, and the braking of the car, stopping said chain running, has little or nothing to do with the radius rods, as I understand it. Moreover, such explanation for the buckling of the rod should affect both rods, whereas it only affected the right rod on my car.

Can you give me a reasonable explanation why a single radius rod, 1 inch in diameter, should buckle at the double-threaded extension joint, when the car has no hard usage, accident or sudden braking? Could the rod have been too far extended in order to tighten a chain which had much better been tightened by removing a link? G. AUSTIN MORRISON, JR.

Without a sketch I do not understand how the radius rod can be under both tension and compression at the same time. Possibly each rod is composed of two members forming a V so that one member is pulling while the other pushes. In this event it would seem that the brake action would be the same either way and as liable to bend a member when going forward as to bend the other member when going backward. However, a single rod of ordinary design is under tension when brakes are applied going forward and under compression when brakes are applied while backing. The strains on radius rods and torsion rods are not well understood by me and I have not found good explanations why one man will get along with a rod 9-16-in. diam. when on an identical machine another man will bend a rod ⅞-in. diam., yet I have seen this result. Brake action is probably responsible for it. A brake that chatters has a very destructive effect, for it grips and lets go and grips again with a series of jerks that are likely to bend or break something. A chain will sometimes climb the teeth of the sprocket and relieve itself by doubling up the radius rod. In such a case it is a question simply of chain or rod giving way. The sudden application of the brake will throw the slack of the chain toward one sprocket and may cause it to climb just as the braking strain is greatest on the rod and the two strains are more than the rod can bear. This seems to me to be the most likely solution. That one rod should bend and not both is easily explained by the fact that when one bent the strain was relieved and this saved the other rod. It is reasonable to suppose that the weakest one went first. If the threads are damaged it is because the rod has been adjusted out too far, otherwise not. Backing one wheel against a curb or obstacle often bends a radius rod and I would inquire on this point.

C. E. D.

The Italian Touring Club, of Italy, is distributing gratuitously to its members corographic maps of Italy, arranged according to the most modern process used for maps, being especially interesting for tourists, giving distances, descents, widths of roads, planimetric difficulties, curves, zigzag crossings, etc., as well as indication of monuments, interesting point of views. The set embraces all Italy, the bordering territories and the islands, and consists of 58 sheets.

Five of the seven events of the race meet of the New York and Brooklyn motorcycle police squad at Empire City track on Saturday, June 1, were won by Sergeant Howe, of the Bronx. The mile championship of the Manhattan and Bronx squads was won by Sergeant Howe; time, 1.39. The one event in which plenty of excitement entered was the one-mile championship of the Brooklyn squad, and was won by Sergeant Tom McDonald, in 1.52 3-5.

Stewart Speedometer

Our Five Year

Absolute Guarantee

WE guarantee each Stewart Speedometer against everything but misuse for a period of five years from date of purchase. This guarantee and warrant covers materials, mechanical construction and accurate operation of the instrument, flexible shaft and all connections. Each instrument is calibrated tested and sealed before leaving the factory. Any instrument returned to us, at our factory, charges prepaid, with seal unbroken, that has failed to give proper service, or failed to register accurately, or which has otherwise proved defective in material or construction, within above mentioned term, will be repaired or replaced free of charge.

No. 3.	Combination	Speedometer-Odometer,	full	size	dial,	(4-inch)	50-Mile,	$	40.00.
No. 4.	"	"	"	"	"	"	60-Mile,		60 00.
No. 5.	"	"	"	"	"	"	90-Mile,		75.00.
No. 6.	"	"	"	"	"	"	100-Mile,		100.00.

We can make immediate shipments on 50 and 60 mile instruments

We are told our new catalogue, just issued, is the handsomest and most comprehensive book on speedometers yet published. It illustrates and describes the interior mechanism so that all may know why the "Stewart" is sought by those experienced in speedometer matters. Copy for the asking

Stewart & Clark Manufacturing Co.

he illustrations herewith are from the Price car, which was placed on the l May 5, 1907, and was finished in haste irst cars commonly are, and therefore vs lever-steering instead of the wheel ch will be regularly fitted. Otherwise "belt-driven Price" was a very fortunate struction indeed, and will go into exten- manufacture almost precisely as here vn.

he car here shown is really the second -driven runabout invented, built and pat- d by Mr. W. C. Price, who has been ely connected with the manufacture and of low-cost motor cars for some years. r. Price believed that advantages of high ortance could be gained by placing a mo- in front, lengthwise of the chassis frame, ing distance of the crank-shaft from th counter-shaft was 30 ins., the crank-sha pulley was 5½ ins. diameter, the counte shaft pulley was 9 ins. dia., and the leath endless-belt was 3 ins. wide. The moto was a "Beaver" opposed pair of 4x4½-in cylinders, giving 12 H. P. at 900 R. P. M The counter-shaft sprocket had 12 teet inch-pitch chain to a 22 tooth sprocket o the rear axle. The rear wheels had 34 1½-in. solid tires and the front wheels we 30 ins. with 1½-in. solid tires. The whe base was 72 ins. The total weight of th first belt-driven runabout was about 8 lbs., the reduction ratio from the motor the drivers was 3 to 1, and the car cou make 30 or 32 miles. The belt drive w very satisfactory indeed, giving a gradu

Fig 1. The Belt-Driven Price Runabout. Wheel base 100 ins.; gage 56 ins.; rear tires 34x1½, front s 30x1½ ins.; all tires solid rubber. The Beaver motor, two 4x4½ cylinders opposed, is placed thwise of the car under the hood in front, and is stationary, with a pulley 6 ins. diameter to take elt 6 ins. wide bolted to the right-hand side of the fly-wheel. This 6-in. leather belt leads to a 9-inch neter pulley on the counter-shaft, which has about 1½ in. fore and aft motion, given by a vertical, hed hand-lever. The countershaft carries a low-speed and reverse planetary speed change, and a ooth sprocket for an inch-pitch chain to a 20-tooth sprocket on the rear axle. Wheel-steering will fitted instead of the lever-steering shown. The weight of this car is about 800 lbs. The price has been fixt, but will be low, perhaps something under $700 for the runabout body and solid tires, something over $700 for the car with a surrey body to carry four passengers, wheels fitted with pneu- lc tires.

transmitting the motor power by a belt countershaft carrying a low and reverse etary speed-change, and then using a cket and chain drive from the counter- t to the full-length rear axle and sleeve, an interposed rear-axle balance gear.

this new linkage the belt takes the place ne clutch, and must be controlled in some so as to make it drive the car or else he motor run free, or nearly free.

his first car his entire motor had a and aft travel of 4 ins. by means of a engagement and a strong slipping driv convincing Mr. Price that he was o the right track. The 3-inch belt had to b very tight to carry the full power of th motor, and the short wheel-base made th car uneasy on rough roads, altho th body was carried on four, 30-inch, full e liptic springs.

The principal faults with this first Bel Driven Price car lay in the difficulties finding wholly satisfactory means for sup plying the motor with gasolene, lubrica

ve for these connection troubles it is
aimed the car was very satisfactory, and
ere are points in favor of shifting the
otor to tighten and loosen the belt rath-
than to move the counter-shaft and rear-
heels, but after extended road trials the
st car was laid aside and the drawings
r the car here shown begun in February,
07, and the car, as shown in Fig. 1, was
aced on the road, as before stated, early
May.

ig. 2. Belt-Driven Price Runabout, front and left
e, showing front axle.

THE BELT DRIVE.

The first motor car to make much of a
ccess, the Benz, was belt-driven, with
o belts, one open and one crost, and
e belt drive in various forms has been
vented" over and over again in the last
or fifteen years, and has been tried out
d invariably discarded, save possibly in
e case of some of the "high-wheelers,"
ere it has taken the place of chains to
e rear wheels. In view of the generally
successful past use of the belt-drive in
otor cars, it would seem to require con-
erable courage to venture on a revival
the belt-driven motor-car in this day
d age of good and cheap chain and gear
ven automobiles.

Mr. Price reasoned that the endless open
t of ample width, on pulleys of sufficient
meter, was an extremely simple and
rable element, of comparatively low cost,
able of soft and easy gradual engage-
nt, and also capable of transmitting all
e power needed to drive a motor-car,
vided that the belt could be easily made
ht or loose without employing objec-
nable means. Mr. Price was well aware
t no tight and loose pulley arrangement
d no tightener or "Jockey pulley" could
made to give satisfaction. This leaves
y one other well-known means of belt

In the second model Mr. Price pla
the countershaft and the rear springs o
rear subframe, guided to slide fore and
between angle iron surfaces bolted to
under edges of his wooden chassis fra
sides, and linked this counter-shaft a
spring-carrying sub-frame to a vert
hand-lever, as previously specified. T
arrangement leaves the motor standing
its fixt chassis-frame position, and pus
the sub-frame carrying the counter-sh
the springs and the rear axles to the r
to tighten the driving belt, or pulls t
sub-frame forward to slacken the belt. B
the belt pulleys are flanged on each si
and the pulleys are also slightly crown
so that the belt runs without touching
pulley flanges when tight.

This belt drive makes an ideal clut
and also serves as a brake to keep
motor from racing. On a level good-r
surface the slack belt has drag enou
from its own weight to drive the
about 2½ miles per hour, and if the
is held by the brakes with the motor r
ning, the idle-belt friction holds the mo
down so that it never races.

The drive is as nearly as direct on h
gear as can be had by any of the comm
ly recognized motor-car propulsion li
ages, all of which employ at least one
termediate element between the cra
shaft and the rear axles.

In the Price belt-drive this intermedi

showing rear axle and temporary springs.

element takes the form of a counter-sh
only on high gear, with a sprocket a
chain drive from the counter-shaft to
rear axles, and does not include the be
gear at any transfer of power.

It thus appears that the Price belt-dr
is one of the very simplest and lowe

ont axle is good, and is abundantly rong for a car of this weight.

REAR AXLE.

This is Price's own construction, and is solid steel-axle, 1½-in. diameter, to hich the right hand wheel is applied by iding it on and retained by a nut on the utside end. Turning of the wheel on the xle is resisted by two keys, 180 deg. apart, razed on to the axle. These keys are ¼-.x⅛-in. above the shaft, are about 2 ins. ng, and enter key-ways cut in the inside nd of the right hand wheel hub. This xle is on Hyatt roller bearings at the ght side, and is carried clear thru e left hand rear wheel hub, which is ronze bushed, and has a long sleeve-hub,

Fig. 6. Belt-Driven Price Runabout, showing the sh, foot pedals, the latched vertical lever which gulates the belt tension, the steering lever, which ll be changed to wheel-steering. The control specions are given in the text.

hich runs on Hyatt rollers in the left nd spring perch. The rear sprocket is t from a solid steel plate. The balance ear here shown has 8-spur pinions.

THE COUNTER SHAFT.

This is a solid steel shaft, 1¼ ins. diamer in plain bronze boxes at each end, xes split horizontally. At the right hand is counter-shaft carries a grey-iron, doue-flanged pulley, 9 ins. dia., to take a inch belt. The pulley is fixt to the aft by a key and set screw. Next inside e pulley is the planetary sliding-cone ıtch, then the planetary gear, low speed d reverse, at the left, with the chain rocket. The planetary brake-bands are ed with Gandy belting. The planetary aring is external and internal, all spuraring, all steel, reverse slower than low ar.

THE CHASSIS FRAME

and inside member vertical, joined at corners by angle pieces 1¼x2½x¼-ins., plied to the inside of the angle steel fr and fixed with 2 rivets 5-16-in. dia., in hot, in each end of each angle p This lines the whole inside of the woo chassis-frame with the underneath steel gle member, 1¼x1¼ ins., and 3-16 thick.

The motor is carried on two crossg of inverted T-section steel, lower men horizontal, 2½ ins. x ¼-in., vertical m ber 1¼ ins. x ½-in., ends bent and riv through to the angle steel chassis-fr underneath member.

THE SLIDING FRAME.

This is all made of the same 1¼ in ¼-in.x3-16-in. angle steel, and consist two side members 60 ins. long, with t cross-members of the same, riveted to side members, the side members having outside member vertical and of a widt slide inside the chassis angle frame. wooden chassis-frame is 30 ins. wide about 116 ins. long, over-all measureme The sliding frame, which slides fore aft about 1½ ins., hand lever action, in the chassis-frame, has three cross-girts, ins. x 1¼ ins. x 3-16-in., angle-steel, member horizontal and bottom men vertical and looking down, so that the of the sliding frame side and cross m bers come together and are fixt by eting. The front cross-member of the ing frame is 27⅛ ins. long, to slide in the angle steel chassis-frame. The in mediate and rear cross-members of sliding frame are 32½ ins. long and stand in 1¾ ins. outside of the chas frame to take the 1¼ ins. wide, half-e tic springs.

The side members of the sliding fr have the counter-shaft split boxes bo to their under sides, and these shaft b es are given universal movement by g ing to avoid binding.

The sliding frame is not fixt in length of 60 ins. inside the angle s chassis-frame, and is worked by a ha lever, latched, which is pinned and bra to a tubular rock-shaft, 1 in. dia., in bra ets bolted to the bottom of the chas frame. This tubular rock-shaft has arms, standing upward, pinned and bra to it, the top ends of these arms be linked to the front cross-member of sliding frame, so that the sliding fram handled at each side, and can be mo squarely against the driving-belt tensio

The sliding frame is not fixed in way to the underside of the chassis-fra

TRUFFAULT-HARTFORD SHOCK ABSORBER

SHIELDS YOU

From the dangers and discomforts of riding on rough roads. They prevent the breaking of springs, save time, tires and trouble. They are an absolute necessity on any car and can easily be applied. It is not necessary to have a master mechanic put them on, we supply all the necessary fittings and furnish blue print without additional charge, provided make and model of car is given with the order. Seventeen prominent manufacturers use them as part of their equipment. Order them right now, you will not be disappointed. We guarantee them. Our booklet goes into the subject more fully.

THE PIONEER THE BEST

Hosted by Google

HARTFORD SUSPENSION CO

the sliding frame is free to come out under the chassis frame, except for the driving belt.

CONTROL.

The brakes as here shown in this first car, are one brake band on the balance gear drum and the planetary gear reverse band. This brake system will be changed to two brake drums, one on the rear axle, and one on the rear-axle sleeve.

The spark regulation will be by a rocking rod and notched-segment-retained hand-lever at one side of the steering post. The throttle is linked to the sliding frame, to increase throttle opening as belt tension is increased, and there is also an independent throttle control by pedal. The sliding frame is worked by a vertical, latched hand-lever. The left hand pedal gives the reverse. The next pedal to the right gives the slow speed. The third vertical pedal applies the rear axle brakes. A small horizontal pedal at the extreme right works the independent throttle action.

IGNITION.

Ignition is by dry cells, a 2-coil box on the inside of the front-board and jump-spark plugs.

LUBRICATION.

Lubrication is by a force feed oiler, with 4 leads, sights on the inside of the front-board.

ON THE ROAD.

The first Price Belt-Driven Car had a short wheel-base, and was on the general lines of the "High Wheelers." The Belt-Driven Price here shown has 100-in. wheel base, a long hood, small wheels and mud-guards and run-board in regulation form, so that it is a very attractive looking little car. Mr. Price had reasons of his own for placing this second model on the road at the earliest possible moment, and did not wait for the special springs designed for it, but placed springs, not of the right length, of form which were available, with the consequence of such hard riding as to make rough-road work a trying operation. A drive of some miles on Jackson Boulevard showed the car to be speedy, but was devoted mainly to demonstrations of the belt-drive control and the action of the belt-drive generally.

The belt-drive stands any kind of handling perfectly well. The most sudden movement that can be given to the hand-lever starts the car smoothly, without any "jerk" whatever. The slack belt gives the car a walking pace of 2½ or 3 miles an hour, belt slipping, which is yet quite a strong drive, so that the car keeps an even slow rate.

Tightening the belt gradually by one-notch advances of the hand-lever gives corresponding speed advances, making the rate as flexible as a disk friction drive. The belt when tight takes the whole power of the motor without slip, and the whole range of speed can be had by simply moving the vertical hand-lever without skill or caution, everything smooth and silent, making this little Belt-Driven Price car extremely handy and suitable for crowded street work.

Fig. 7. Belt-Driven Price Runabout. Plan of chassis, showing the location of the engine in the frame and the arrangement of the belt drive to the planetary shaft.

Monarch Motor Car Company has secured a site of fifteen acres at Chicago Heights, Ill., and will build a large factory there.

The speedwell Motor Car Co., Dayton, O., has appointed Walter Keenan as their general manager. Mr. Keenan has for a number of years been general managed of the Standard Oil Co. interests in Dayton, O.

Hayden H. Eames, of Cleveland, Ohio, who for a number of years had the selling agency for the Garford Co.'s productions, has accepted the general management of the Studebaker Automobile Company, South Bend, Ind. Mr. Eames' business, of Cleveland, will be taken over by a newly-formed concern, known as the American Distributing Co.

GET READY FOR

1908

The sale for Cadillac cars has always been so great that our factory has never been able to fully meet the demand and we have, therefore, not been in a position to take on many new dealers.

We have, however, recently enlarged our manufacturing facilities and shall be in a position to make arrangements with a limited number of new dealers in unoccupied territory.

It is not necessary here to go into details about Cadillac cars. They are the most popular and easiest cars in the world to sell. Their unequaled dependability and economy of operation and maintenance is so universally known that the Cadillac usually receives the first consideration of a prospective purchaser, the question being whether he could get one.

If you are an automobile dealer or expect to take up the business, your success depends upon handling cars that give satisfaction and that you can sell in increased quantities year after year.

Cadillac dealers, as a rule, are the most successful dealers because they can sell more of them than any other and because it takes less effort and less expense to sell a Cadillac.

The line is as follows:

10 H. P. Runabout	**$ 800.00**
10 H. P. Four Passenger Car	**$ 950.00**
10 H. P. Enclosed Coupe	**$1350.00**
20 H. P. Four Cylinder Runabout or Touring Car	**$2000.00**
30 H. P. Four Cylinder Touring Car	**$2500.00**

Now is the time to get ready for 1908 by selling some Cadillacs this Fall and getting trade started which no other car can take away from you.

300 pounds to the square inch. The maximum tank pressure can be varied by varying the spring load of the tank-charging cylinder valve; the heavier the valve spring the lower the maximum tank-pressure and the lighter the valve spring is the higher the maximum tank-pressure becomes. The tank pressure is piped to a gage on the inside of the dashboard, under the driver's vision. The tank-charging valve is spring loaded, so as to give a maximum tank-pressure of about 150 pounds, and the tank gage will commonly show somewhere from 100 to 125 pounds The highest possible tank pressure is obtained when the motor is doing its hardest work, and so has its highest cylinder pressure.

Fig. 3. Pressure-valve, screwed into the top of the rear cylinder compression chamber. The Triumph motor compression is 70 pounds gage, and the pressure valve is spring-loaded to something more than the motor cylinder compression, so that the valve cannot be lifted by compression of a full charge, nor by the fired pressure of a very much throttled charge, hence nothing passes from the motor cylinder to the pressure tank thru the pipe, P, save when the motor is working under load. The valve is not water-cooled, as now used in the 1907 Triumph motor. The passage, R, from the compression space to the valve, is oblique. It was first made vertical, and the valve then became injuriously hot. The passage was then given a right angle turn and the valve then did not give satisfactory tank-pressure. As here shown, with a large V-groove in the bottom of the valve body, and an oblique passage, R, from the V-groove to the valve-seat, the valve does not over-heat and the tank-pressure is quickly gained and is always sufficient to start the motor See Fig. 4. Triumph 1908 water-cooled pressure valve construction.

The pressure tank has only one opening in it, that which takes the ½ inch pipe to and from the tank. This pipe either conveys the products of combustion from the rear cylinder to the pressure tank, or else leads pressure from the tank to the intake valve of the two rearward cylinders when starting the motor. There is no provision whatever made for giving the tank an initial charge of compressed air, and the motor is fitted with the usual starting crank, by which it must be started when there is no pressure in the tank. When the motor is started by the hand-crank and the car is driven on the road so as to give the motor some work to do, the tank gage will commonly show 100 pounds, at the end of the first ten minutes or so of running, and the harder the engine is worked the sooner the tank pressure is gained.

The motor will start with about 20 pounds tank-pressure, and with 100 pounds tank pressure, car standing still, it is claimed the motor can be started ten times before the pressure will fall too low. The tank gage drops from 5 to 10 pounds, more or less, each time the motor is started and the tank

Fig. 4. Triumph self-starter pressure valve, water-cooled, direct passage, R, from compression chamber to valve, V. W-W is cooling water, V, valve; P, pipe to pressure tank. R, direct vertical passage from the cylinder compression chamber to the valve, V. The body of the valve is squared to prevent passage of burned gases to the tank-pipe, P. In this description the pressure is mentioned as "air" pressure, but it is, of course, not atmospheric air, but the burned product of charge combustion in the cylinder.

pressure is not replenished by the motor running light, on a throttled charge, with the car standing still. The motor must be doing some work to have cylinder pressure enough to lift the tank supply-valve against its spring load and so begin to fill the tank. With a 4-cylinder 4-cycle motor, cranks

Fig. 5. Vertical section of the Triumph self-starting cylinders, the rear dual-unit of the 4-cylinder motor, in two planes, thru the middle of the rear cylinder, and thru the valve-seats of the left cylinder, both planes vertical. The chamber, C, below the right hand valve seat, takes the integral in-take valve. See Fig. 7. See also Fig. 6.

180 degrees apart, the motor may stop with the cranks on the center, and in this case the air-start cannot start the motor. This objection obtains in all self-start systems de-

All my talking about the "Maxwell" is only the whisper of a breeze when compared with the whirlwind way the "Maxwell" talks for itself in actual performance.

Ever since the "Maxwell" was first designed—by Mr. J. D. Maxwell, the b automobile designer in America—and was put on the market, it has been speaki for itself by its deeds.

The "Maxwell" won endurance contest after contest, mountain climb af climb, won the Deming Trophy in the Glidden Tour, of 1906, then won the worl 3000-mile non-stop record—which it still holds—and so pursued its triumpl march of victory right up to its recent sweeping of the field at Wilkes-Barre a Bridgeport hill climbs, and its coming out with a perfect score in the fam "Sealed Bonnet" Contest.

These are the things that prove the work of

"The Maxwell"

to you—to the man who wants an all-around, general, always-to-be-depend upon-utility.

The "Maxwell" is never known to fail its owners—over 7,000 deligh "Maxwell" owners throughout America will gladly testify to this.

Complete literature telling of all the splendid details of construction wh have made these feats of endurance possible, will be mailed you free if you w address Dept. 7. Also, if you will address me personally, I shall be glad to se you a personal letter of introduction to the "Maxwell" dealer nearest you.

Tell him to give you a ride in the "Maxwell" over the toughest piece country that you know—that will show you.

Benj Brisco

pending on using elastic vapor from a pressure tank to start all or a part of the motor cylinders, where the cranks are 180 degrees apart.

This objection is not serious, however, for if the throttle is opened before the motor is stopt the motar will almost always, if not constantly, stop with a partly comprest charge in two of the cylinders with both cranks at 90 degrees from vertical, which is the most favorable crank-position for a comprest air start.

When the starting-cylinder cranks do stand still on the center, due to a sprung crank shaft or binding from other causes, then the crank-shaft must be given part of a turn with the hand-starting crank.

THE TRIUMPH SELF-STARTING ACTION.

The really automatic motor starting device must depend on some reservoir of power. Those "self-starting devices, so called, which depend on muscular power thru some linkage which can be operated by the driver without leaving his seat are not automatic, and are not here considered. In the Triumph two valves are placed in the pipe from the cylinder to the pressure tank; the first valve is close to the cylinder, opens from the cylinder to the tank, is spring-loaded and closes from the tank to the cylinder, and, save

Fig. 6. Triumph self-starting cylinder, vertical section thru exhaust valve. See Fig. 5.

for the spring load, would always open from the cylinder to the tank and close against passage of fluid from the tank to the cylinder. A stop-valve, hand-actuated, is placed in the pressure-pipe, accessible thru the driver's floor space. This valve is opened and closed as may be desired, principally to certainly retain tank pressure where the car is to be laid away for a time, and will not be considered hereafter, as it has no functional relation to self-starting.

The cylinder-valve load is important. Suppose the maximum cylinder pressure is 250 pounds. Then with no valve-load the tank pressure would rise to 250 pounds, and would remain at that pressure until the tank was opened to discharge some part or all of its contents. Hence, the smaller the valve-load the greater the tank pressure. Sup-

Fig. 7. Six of the 8 valves for the 4-cylinder motor are of ordinary form. The intake-valves for the starting cylinders are made with an ordinary valve head on top and a piston valve with one eccentric packing ring is formed, integrally, 1¼ inches below, on the valve stem. The piston valve slides in a cylindrical chamber below the valve seat, the space below this piston being open to the air. The comprest air from the tank enters between the intake-valve head and the piston valve, so that the air pressure does not tend to much lift the intake valve, and so avoids the necessity for a very heavy closing spring on the air-intake valve stem. See Figs. 5 and 6.

pose, now, that the cylinder pressure maximum is 250 pounds, as before, and that the valve is loaded to 125 pounds. Then the tank will be filled to 125 pounds pressure by continued working of the engine at maximum cylinder pressure and after that nothing more will pass from the cylinder to the tank, because the spring-load of 125 pounds and the tank-pressure load of 125 pounds, taken together, equal the maximum cylinder pressure.

To use this tank-pressure for starting the motor, communication is opened between the pressure-tank and the intake valves of the two rearward cylinders of the 4-cylinder motor by means of a pedal-actuated pressure valve. This starting pedal is placed about the middle of the driver's floor space, and when pushed forward the pedal opens a valve against the tank pressure and admits this pressure to reach the intake-ports of the two rearward cylinders. To prevent the tank-pressure from blowing through to the carburetor, a carburetor pipe-valve is provided and the starting pedal is so linked to the two valves as to first close the carburetor pipe to the two rearward cylinders, and then, by continued forward motion of the starting pedal, the tank-pressure admission valve to the two rearward cylinder intake valves is opened. These two intake-valve cams must be changed so as to admit tank pressure throughout the entire down stroke of each of the two rearward pistons, and the exhaust valves for these pistons must be open to the atmosphere thru the entire upstrokes of these same pistons.

The intake-cams of the forward pair of cylinders are unchanged for starting, but the

The New Semi-Racer Proves Itself

After it had been on the market less than a month the new Haynes Semi-Racer won its first competitive test in the 200 Mile Endurance Run of the New York Motor Club, June 6th. Over roads which recent rains had put in horrible condition, under conditions that required an average of 20 miles an hour, a very high average for touring, this Haynes Runabout won in its class. It reached its destination at Albany ahead of time, and in fact through a mistake of the timing was permitted to cross the line too early and was penalized. Experienced drivers said that the run was the hardest endurance test which had ever been held in this country for stock cars.

The Haynes led all the cars during most of the race, beating the high powered touring cars at most of the controls.

The chassis of this car is the same as our Model "S" touring car with all the improved and advanced features which have made our 1907 models famous. It has the patented roller pinion and sprocket direct drive, solving satisfactorily the old problems of rear-axle strains.

It is impossible for the driver to injure the car by careless or rough handling, because the master clutch cannot be made to take hold otherwise than softly, and the exclusive transmission control allows change of gear without releasing the clutch by a single movement of the hand with no possibility of burring or stripping the cogs. The Haynes positive cooling system makes overheating unknown.

Unlimited speed, perfect comfort, a silent engine, a transmission, and snappy style, and a name that is thirteen years old—these are what can be had in this new semi-racer.

No one can doubt the supremacy in its class of **"the latest model from the oldest maker."** Price $2,500.

OTHER MODELS:

Model "T", the Vanderbilt Cup Racer Chassis, 50 H. P. Touring Car, seating 7, $3,500.

Model "S", 30 H. P. Touring Car, seating 5, $2,500.

IT IS not the candle power of your light, or even the size of your lamp, that determines the illuminating power of your searchlight. It is the refraction of the rays. The problem is to compress these light rays into a solid stream of light. If the light is diffused, you will not get the required illumination.

Bausch & Lomb Searchlight Mirrors

Add about 50 per cent. light efficiency to the lamp. They have been worked out scientifically to condense the light rays, and the light that ordinarily is diffused in all directions is concentrated into a powerful beam capable of projecting itself a great distance.

¶ Insist upon having a lamp fitted with the Bausch & Lomb Searchlight Mirror, and *see* the difference. Every mirror is stamped B. & L. on its face.

R. E. DIETZ COMPANY

LARGEST MANUFACTURERS OF LANTERNS IN THE WORLD

LAIGHT STREET — Established 1840 — NEW YORK, U

oard. It was the first really warm day and southwest wind blew warm in our faces as e wallowed thru the bottomless quag-ires which lead from Cragin Station to avement on a run to Elgin to see how the lf-starter works on the road. We drove eadily at 25 to 30 miles where unlimited, ver the rough, crooked, hilly road, and save or rather stiff rear springs and no toe-oard and occasional dashes of rain stinging ur faces, the run was a faultless demonstra-on. The 1908 Triumph motor will be four linders, 4¾x5 ins., much more powerful an the 4¼-inch cylinders which pushed us Elgin and back.

As the car had no inside mud-guards in ont and there were plenty of puddles on e way we were well splashed, tho it is nly fair to Mr. Halladay to say that he rotected the Observer's seat from mud and ater as much as he could.

The starting-tank gage showed 60 pounds the shops, and it was soon raised to a undred on the road, and there was always om 100 to 125 pounds shown by the gage. he motor was started with the car standing n the factory floor by a push of his hand n the starting treadle, which the observer id not see, altho standing close beside e car. Twice, in wallowing thro the ottomless mud, the motor was killed, and the motor was stopt by the switch self-start was prompt. We made a nun of trials of the self-starter on the re run, and in every instance where the m was stopt by switching off the current self-start was prompt.

When the motor is "killed," however, the clutch in there is a chance that the en may stop on center, in which case, of cou it would have to be slightly moved be the tank pressure would start it. But a condition is rarely met and need not considered.

With 100 pounds pressure in the tank, standing still on the road, we made successive starts of the motor, stopping motor with the switch, all of these six st were prompt. At the seventh attempt crank-shaft stopt on the first center, the self-start was completed by tank-pres as soon as the crank-shaft was moved the hand-crank off the center. The gage index dropt about 10 pounds o for each successive start. Taken altoget the self-starting arrangement showed to g advantage, and fully confirmed the observ previous opinion of its merits, and also convincing evidence of the very great venience and practical value of such a de for car-motors.

motor studs, and a leather belt is loopt around the dynamo and motor studs alternately and laced together. This makes a soft, silent drive from the motor to the dynamo, or from the dynamo to the motor.

After the Sultan motors show 32 horse power at 1250 turns a minute they each have 10 hours of run at that speed, turning the dynamo against the weight resistance, and if the motor goes thru this all right it is then past to the chassis assemblers.

The French horse power is 0.9863 of an English or American horse power, and the table here given, from a Sultan shop's blue print, translates French motor ratings into English H. P. equivalents.

This Sultan motor testing equipment was built by the Otis Elevator Company, Springfield, Mass., who are prepared to supply the trade.

Every car-motor builder should know what his motors can really do, and with such a testing plant as is here shown there is no difficulty in finding out what a car-motor horse power really is.

Thomas to Build Entirely New Detroit Plant

The E. R. Thomas Detroit Co. recently celebrated its first anniversary by the announcement of completed plans for the erection of an entirely new plant about four miles from the present plant, which, tho in operation but one year, has been enlarged from time to time to keep the output up to the demand for Thomas Forties. The new plant will be ready for occupancy September 1, and will cost, fully equipt, $250,000. It will stand on Jefferson avenue on one of the best spots in Detroit for manufacturing purposes, and the company will have plenty of room for future enlargements. Reinforced concrete construction will be employed thruout and the unit system of building will be followed so that new units can be added as needed. The main building will be 400x60 feet, 3 stories high.

Then there will be a separate power plant of large dimensions, a stock building and a testing building, besides a large garage, thoroly equipt. In all there will be about 100,000 sq. ft. of floor space.

The accompanying reproduction shows what the new plant of the E. R. Thomas Detroit Co. will look like when complete. The Thomas people own two city blocks of frontage on Jefferson Ave., where the new plant is being built and is well under way. The construction is all of reinforced concrete. They expect to finish the plant and have machinery running by the first of September. They inform us that this year's output of Thomas Forties is now practically complete, as the last car of the season's production of 503 runabouts and touring cars will be shipt on the 15th of June.

E. R. Thomas, Detroit Co.'s, new plant, its appearance when complete.

"Reno" Fillers

Reno Brothers Paint Co., Pulaski, Penna., are manufacturing a high class filler for use by automobile builders for priming, lead coating and as a rough stuff. It is made in two grades, viz., raw and burnt. It sand papers freely, giving a perfectly non-porous surface and allows the varnish to retain its lustre for a great length of time, it is claimed. The burnt is made by roasting it several hours in ovens, at a high degree of heat and makes a very desirable ground for lakes, carmines, vermillions, etc.

Motorists in taking their own cars apart should be careful to mark every bolt and nut so as to put it back in the place it was taken from. It does not do even to mix bolts of the same size. For the small parts envelopes afford a convenient means of keeping them separate for identification, but the use of shipping tags is safest for most parts. The projecting ends of bolts should be wiped before taking off the nuts. Unscrewing and screwing with dust and sand on the thread is bound to result in cutting down the thread and may be the cause some day of an unfortunate breakdown. Before mounting the nuts a rag should be passed thru them, and, as a further precaution, a drop of oil or a little grease should be put on the ends of the bolts.

Have You A Practical, Working Knowledge of an Automobile's Principles?

If you are not absolutely sure that you have, don't lose a minute—write in at once for the free prospectus describing the series of eight splendid lectures now offered by The Correspondence School of Motor Car Practice, of Tarrytown, N. Y.

The success of these lectures has been so pronounced, since we first announced them in this publication a short time ago, that we have had a hard time in keeping up with our orders.

However, we have gotten things straightened out now so that not only the requests for free propectuses but the orders for the lectures themselves will be promptly taken care of.

These lectures are the first set of actually practical instructions that has ever been prepared for the understanding and running of a motor car. They were gotten up by the Technical department of the Maxwell-Briscoe Motor Co. (Makers of the "Maxwell") under the personal supervision of H. A Grant, M. E. They cover exhaustively the history of motor driven vehicles They define every part and principle of a gasoline engine and give pointers on the care and practical operation of a car.

These lectures embody advice worth a lot of money to anybody interested in an automobile.

An unusually valuable feature about this series is that they are illustrated with about **fifty original drawings** of motors, parts, etc. No automobile owner, driver or student of automobile construction can possibly afford to be without this remarkable set of lectures.

Instead of costing from $25 upward, as the ordinary course in a correspondence school does, and instead of requiring many weeks for completion, this course may be obtained **complete, for only $5,** and take only so long to learn as the student chooses to take in learning them. Accompanying the course is "The Making of An Automobilist," by H. A. Grant. It is a fine book of 141 pages, fully illustrated and bound in Morocco.

We make a special offer to owners of Maxwell cars who will write to us giving the number of their car, and date of purchase. To such owners we will give the complete outfit for only $3.00, to cover cost of printing, binding and mailing.

A Prospectus of the Course Will Be Sent Free On Request.

5 to repair a GOODRICH Quick Detachable TIRE

5 to repair OTHER MAKES

CENTRAL PENNSYLVANIA AUTOMOBILE COMPANY

General Agents for Central Pennsylvania

HIGH GRADE CARS, ELECTRIC, GASOLINE AND STEAM

Harrisburg, Pa. May 17, 1907.

Gentlemen:—In our recent Endurance Run, pulled off under the most trying circumstances, the roads being notoriously bad, and the weather worse if possible, we had on the White Steamer, Car No. 6, a valuable demonstration of the advantages of the Q. D. Rims. The time required in repairing our first puncture was not measured accurately, but we repaired the second one, and were again in the race, after four minutes. We next found a ten-penny wire nail driven in clear to the head. In this case, we took the tire off, put in a new tube, inflated it with the air pump of the car, in three minutes by the observer's watch, which we believe was "going some" in this line of work. *Our less fortunate competitors were, in many cases, three times that long in doing the same work.* Some cars in this run suffered as many as eight punctures and blow-outs, which accounts for the many bad scores shown on the Official record, and we considered ourselves fortunate in having Goodrich Q. D. tires.

Yours respectfully,

CENTRAL PA. AUTOMOBILING CO.

I. W. D.—M. M. T. I. W. DILL.

Bevel-Edged Front Glass

Having recently ridden on a fine car, inded to be elegant throughout, in which e front glass, in front of the driver, was veled for about an inch all round inside e sash, it seems needful to mention this ror, as thick panes of glass are so genally beveled, and the beveled edge adds so uch to the appearance of the window that hers may once make the same blunder, ough no one would be likely to do it twice. am not very familiar with front-glass cars, t have never before noticed the bevel edge ywhere, and presume that the flat pane of ass is the rule, and it may be that the vel edge has never been placed on the

tions, and is therefore highly objectional

The front glass should be perfectly p flat plate, as life often depends on driver's correct judgment of the distance tween himself and other objects, either tionary or in motion, and anything wh misinforms the driver as to the true loca of objects on either side of him should carefully avoided, and instantly remo when discovered. I may add that the signer of the particular car referred to not seem to regard the beveled edge of front glass as a serious matter, hence warning may be useful to others who do fully appreciate the possible results of a driver's misplacement of objects with wh

changed and improved. This air-oning device, as described in our issue n., 1907, page 324, consists of an air-tight ze cylinder, in which a piston moves ward and upward with the action of springs, the inclosed air by-passing end to end after cushioning and ab-ng the shock. On smooth roads the ssing action is unimpeded, allowing prings free action, but for excessive ons the cushioning effect increases ressively. By the new arrangement y-pass holes the instrument can be ly adjusted, not only to the load or nt of car, but to match the strength ength of stroke of the springs.

e constructional changes will be ght out in describing the action of the ument as now put out. In the accom-

But if the piston is forced down by heavy shocks so as to cover some of the holes, then its downward motion progressively cuts off the air exit and increases the resistance to motion in proportion to the spring compression. If the shock is severe enough to force the piston below the last hole the confined air acts as an elastic cushion, preventing the spring from going too far, thus taking the place of the usual rubber bumper. On the return the comprest air at the bottom first assists the upward motion, but only enough for the springs to open sufficiently to take another shock if there should immediately be another; then the upward motion is resisted, preventing the unpleasant and destructive upward toss so often noticed by tonneau passengers. This action is ef-

The latch on top to hold the box down nen the tonneau is closed is a new feature, that it prevents all clatter on bumpy roads. ne makers admit that when open it is not wholesome as a big side door tonneau, but is just as comfortable to sit in, and it does t have to be open when not occupied. This a very desirable feature on a car that is ed mostly as a runabout.

iller's Power Tire Wrapping Machine

The accompanying cut illustrates a new wer tire wrapping machine manufactured Chas. E. Miller, Anderson, Ind., the ief advantage claimed for it being that it ll wrap much tighter and evener than is ssible to wrap by hand.

As seen from the illustration the machine nsists principally of a revolving ring upon ich is mounted a roller carrying the cloth tight or loose as desired. It is necessary have a number of spools so that whe spool is empty a full spool can be quickly in place. The end of the cloth is wrapt o around the tire by hand, then the machin thrown in gear and the spool revolves aro the tire. The machine is instantly stopt started by a foot lever. An opening is m

finger piece. Supported in the coil is an nature 3, of elongated shape provided h pivots 4, supported in suitable bearings, owing the armature to oscillate in the ax- plane of the coil. Upon the outside of coil and extending parallel to the con- ution thereof is secured a permanent mag- 5, which extends a sufficient distance und the coil to form a magnetic field for armature. This magnet is screened m the coil by an interposed strip of rub- cloth 6, and is secured to the coil by a gle screw and nut 7. Attached to the nature is the balanced index hand 8, which nade of a thin strip of aluminum and ex- ds with its long arm thru a slot 9, in the l plate 10, and to the index carried upon dial plate and which is suitably calibrated indicate from zero up to the maximum ication for which the instrument is de- ned.

"Pfanstiehl" X-Ray Automobile Spa Coils

The Pfanstiehl Electrical Laborato North Chicago, Ill., have been experime ing for the past five years on induction co with a view to produce a flame instead the ordinary spark. This they claim to ha accomplished in their X-Ray coil, a fo cylinder type of which is shown herewith

The kind of spark produced by their co is what they call the "Caterpillar Flam which they claim is from 5/8 to 3/4 of inch long on six volts and one inch on high voltage. The secondary coil contains fo teen sections connected in pairs, of ve heavy wire, and the primary circuit a ve fine wire, these two compartments of coils being so balanced that the best pos

The "Pfanstiehl" Four-Cylinder Coil, with sw showing unit construction, cover removed.

ble results are obtained, viz.: a minimum current consumption with a maximum spa The armature is designed to give a sure a rapid vibration. Large contacts of Iri Platinum are used. The secondary windi is guaranteed not to burn out on any cu rent. Each coil is given a thoro test on volts of battery current. As a further pro of the intensity and volume of dischar they claim that X-rays can be produc with any one of their units in connecti with a small X-ray tube and ten volts battery current. Besides the four-cylind coil illustrated they also make them w one and two units in a box. Each coil provided with a switch lock to prevent o siders meddling with the coil when car left standing alone.

pany, of Detroit, Mich., manufacturers of auto chimes and marine whistles, etc., are placing on the market a very advanced combination muffler cut-out and safety relief which should appeal to every user of an automobile, as it is very practical and durable and may be quickly and cheaply attached.

The valve body, lever and bracket are made of malleable iron. The valve is ground and has three guides, thereby insuring a tight fit and positive seating at all times.

The safety relief feature is governed by a nut and oil-tempered spring. The spring,

The "Gray-Hawley" Combination Muffler Cut-out and Safety Relief.

being placed on the outside of the valve and never coming in contact with the exhaust gases, does not become heated and lose its temper. It should be adjusted so the valve remains closed under normal conditions, but will open whenever a charge is exploded in the muffler, thus saving the muffler from severe strains and possible destruction.

The bracket swivels on the lock nut and can be turned to any desired position by simply loosening and tightening this nut.

The lever is also reversible. This adjustable feature means that this cut-out may be very easily attached to any make of car without the use of bell cranks or pulleys. The cut-out is furnished in any size from 1 inch up to 3 inches, and the price ranges from $2.50 up.

The Universal Repair Bench

A very useful combination repair bench

wood top mortised and glued, makin joints absolutely tight, and mounted it a special bench block and univ swivel vise. The bench is 2 feet wi feet long and 3 feet high. In the lo part the Universal Repair Bench has drawers of two sizes, a cupboard plenty of shelf room for the placin tools, all kinds of oil, cans, repairing fits, rubber tires, attachments, etc.

The Universal Repair Bench, a handy tool fo garage repairman or experimenter. It is equipt a special combination bench block and a uni vise. Price f. o. b. Rochester, N. Y., $50.00.

The bench block is fastened to the end. This tool is entirely new in de being made specially for use with bench. It is a combination tool of g value in repair work, being used for b ing, straightening hammering or form metal. This block is sold separately $10.00. The specially designed swivel is reinforced for heavy work, but is cate enough to handle small pieces can be used in any position at any a and is locked in position by a hand cl operated by a bar similar to that opera the vise screw.

The outfit complete ready for shipm F. O. B. Rochester, N. Y., sells for $5

The Holley 1908 Carburetor

The Holley 1908 carburetor, which is claimed to be an automatic carburetor without moving parts, is manufactured by the Holley Bros. Co., Detroit, Michigan.

In the Holley carburetor a high air velocity is obtained in the mixing chamber by applying the principle of the Venturi tube. This feature, tho not itself original with the Holley carburetor, is important because it is seldom correctly applied, it is claimed. The true Venturi tube acts to discharge a liquid or gas with a velocity thru the smallest section of the tube greater than the velocity due to the head alone.

Referring to the sectional views, A is the air inlet thru which air passes downward and up thru a U-shaped tube, which is constricted at its lowest point. In the floor of the U is the gasoline orifice B, which is regulated by a needle valve, E. The carburetted mixture passes thru a butterfly throttle valve and on to the motor by the connection C. The float chamber surrounds the lowest part of the U, and has an annular cork float, J, which controls the gasoline valve L, thru a lever, N, pivoted at K. The U-shaped mixing chamber is merely the Venturi tube in a special form, allowing a very high air velocity to be obtained at B.

The gasoline level in the float chamber, instead of being slightly below the orifice B, is about one-eighth inch higher, and it is in this fact that a radical departure lies. In the new Holley carburetor there is a puddle of gasoline one-eighth inch deep in the bottom of the U when the motor is at rest. Consequently, when the motor is starting or running very slowly, the air does not have to lift the gasoline at all, but simply draws over the puddle and is carburetted by surface evaporation. As the throttle is opened and the air velocity increases, the puddle is gradually swept away by the strong air current over it, thus reducing the surface area of the puddle and maintaining constant proportions in the mixture. At the higher speeds the puddle is wiped out entirely, and a spray of the ordinary sort takes its place.

To start the motor, the float is deprest by the primer H. To prevent the mixing chamber from being flooded to excess, the drain pipe D is provided. The throttle valve is operated by the lever F, and the adjustable stop screw, G, permits regulation of the opening for minimum speed.

The "Eco" Acetylene Gas Torch

The accompanying cut illustrates the Eco Acetylene Gas Torch, for the initial heating of the vaporizing tubes of steam automobiles, and for lighting the pilot burner of same; or, in other words, for firing up steam automobiles. It is made by the Eco Manufacturing Company, of 53 State street, Boston, Mass.

In the illustration, the torch is represented as attached to the boiler of a Stanley automobile, with the burner of the torch in position to direct its flame upon the pilot vaporizing tube.

The torch consists of a stand which may be attached to the boiler or burner of an automobile, depending upon the style of same, which stand is provided with a swing or flexible joint, to which one of the swinging tubes may be connected, and with a union connection by means of which the

The "Eco" Acetylene Gas Torch.

stand is connected by suitable piping with the source of gas supply. Interposed in the piping is a needle valve, not shown, which controls the quantity and velocity of the gas as supplied to the burner tip. A second swing or flexible joint connects the burner tip by suitable tubing to the first swinging arm; the arrangement of the parts being so that the burner tip may have quite a large range of movement and may be positioned as desired. The swing joints are packed with suitable packing so that they will move with sufficient friction to hold the burner in any desired position.

The Eco Acetylene Torch is made in several different styles for use on the different makes of steam automobiles, with two swing joints for the Stanley, Ross and Clark steam autos; and with one swing joint for the White, General Electric and other makes having flash boilers.

Owing to the peculiar properties of acetylene gas the torch had to be constructed to furnish the gas under a pressure of ten or more pounds, and was found to work best when the gas pressure was about thirty pounds, so that to operate it satisfactorily it must be used in connection with a storage tank, or the Eco combined generator and storage tank, made by the Eco Manufacturing Company, manufacturers of the torch.

In operation the torch is swung so that the flame will be directed against the pilot vaporizing tube, and the flame allowed to remain on said tube from fifteen to twenty seconds; then the volume of the flame is reduced by the needle valve and the torch burner swung over until the flame is lighted in the hole in the burner casing provided to light the pilot burner, so that the flame will be projected in the path of the vaporized gasoline as it flows out of the pilot burner and lights the same.

The advantages claimed for the Eco torch are that the pilot vaporizing tubes can be heated and the burner lighted in from twenty to thirty seconds; that the flame of the torch is not materially affected by wind or rain, and that it is clean and safe to handle and is also very economical.

The "Jordan" Combination Tool and Battery Box

A handy and very useful adjunct to help the automobilist in keeping his tools and batteries in a safe and convenient place is the Jordan Combination Tool and Battery Box, manufactured by E. B. Jordan, Jr., No. 873 Union street, Brooklyn, N. Y.

This box is particularly suitable for high-priced cars and is constructed so as to be waterproof. It is made of seasoned lumber, strongly built, and can be bolted to the running board and serve as a step. At one end a space is provided for holding storage or dry cells. The remainder of the box consists of four drawers, so designed as to hold all the tools and small parts necessary for touring. The drawers are made in different depths from 1¼-inch to 2½ ins., so there is no waste room. The door over drawers and cover to battery box are provided with polished brass hinge hasps, each having a padlock. The size of the box is 24 inches long, 9½ inches wide and 9 inches high.

The box is painted in all standard colors, but will be painted to match any sample submitted to suit purchaser's car. The list price is $12 painted; $1 allowance is made if box is to be furnished unpainted.

W. T. Helfer, formerly New England manager for the Diamond Rubber Co., has connected with The Springfield Metal Body Co., of Springfield, Mass.

R. E. Olds, president of the Reo Motor Car Company, of Lansing, Mich., is spending two months in Europe establishing agencies.

The Heath Dry Gas Co., 1623 Broadway, New York City, manufacturers of the Heath dry gas carburetor, have informed us that they have entered into a contract with the Ohio Brass Co., of Mansfield, Ohio, by which the latter company has taken over the manufacture and marketing of the "Heath" carburetor on a royalty basis.

WOODWORTH

ADJUSTABLE TREAD DETACHABLE

The value of Woodworth Treads to the tires, the automobile and the automobilist cannot over-estimated. They protect the tires more completely, more positively and more economica than any other existing device can do it. In protecting the tires they give equal protection the automobile. They make punctures, skidding and sluing impossible. They make the car where it is sent and prevent accidents. In preventing accidents they also protect the persons, t lives of the occupants of the car. No automobile should be run for a single day unequipped wi Woodworth Treads. No car is complete, no car can be run economically, no car is safe witho Woodworth Treads. The magnitude of their importance is not to be forgotten as you val your tires, your car, your money and your own personal safety.

Woodworth Treads are made and carried in stock to suit any size, style or make of pneuma tire.

Woodworth Treads for Solid Rubber Tires.—Special Woodworth Treads are made to order solid rubber tires. In ordering give the outside circumference of your tire and rim, measured wi a tape measure; also the width of the tire tread where it rests on the ground.

Write to-day for booklet, "Safe and Sane Automobiling." Sizes and prices are as follows:

Helmet Oil

WILL SOLVE YOUR LUBRICATION TROUBLES

Few automobilists realize the importance of good oil.

They know in a general way that a car needs oil—and see that their car has "enough."

But good lubrication in an automobile isn't a matter of quantity—any more than it is in a watch.

After the man cleans your watch he oils it carefully with a special oil—that won't clog or gum or eat the metal—but will simply lubricate until the oil is evaporated.

Now you know that the watch will run for a long time after that—without attention—because the *oil is made for that purpose*—and we say to you "You can get the same results on your car if you'll go at it right—and here's how"—

Helmet oil is to an automobile what the finest watch oil is to a watch—Bearings packed with Helmet Oil need no attention except at long intervals—same as a watch—because—

The same applies. It is made with that end in view. It won't run out of the bearings because it won't melt under 175° F. It won't freeze. It doesn't contain an atom of pitch or gum or acid. It simply preserves a thin film of perfect oil between two frictional surfaces—until it just naturally evaporates.

That is the most perfect form of lubrication known.

That is what Helmet Oil is doing daily on the finest cars in the world.

That is why it requires just half—50 per cent. less—Helmet Oil to run your car than any other brand.

This is no accident. It is the result of a scientific combination of high grade, refined ingredients *in exact proportions*. Helmet Oil will lubricate every bearing of your car.

But don't take our word for this· Simply take advantage of the following liberal offer.

You'll never have the limit of satisfaction with your car until you do.

WE POSITIVELY GUARANTEE HELMET OIL

Send us your name and address and we will see that you get a sample cup of Helmet Oil. Try it 10 days. If it does not save you 50 per cent. over any soft oil you've ever tried—return it to our nearest agent—and no charge will be made for the oil used.

Trade Printed Matter

The "Pittsburg" Automatic Vise & Tool Co., Gen
eral Offices, Pittsburg, Pa., have just had publishe
and sent out to the trade, a very handsome and uniqu
book advertising the Pittsburg Two Way Vises, an
dealing particularly with their "High Speed" Benc
Vise. The cover design is a vivid mill scene wit
the Pittsburg vise prominent in the foreground, sur
rounded by a wreath of Victory.

Morgan & Wright, Detroit, Mich., very patrioticall
celebrated the Fourth of July by issuing, in the nam
of 99 3-10 of the users of M & W tires, a declaratio
of independence printed in red and blue on whit
paper and bordered in red, white and blue. A littl
American flag was placed across the corner of eac
copy. The "declaration" was, very naturally, in th
form of a boost for M & W tires.

The fourth of their series of route books has jus
been issued by the White Co., of Cleveland, Ohio, an
contains full particulars regarding the "air line"
route to the Jamestown Exposition.

The Logan Construction Co., Chillicothe, Ohio, hav
issued a neat folder to disseminate the story of th
run of a Logan "Blue-Streak" runabout from th
"Lake to River," that is, from Toledo to Portsmouth
The distance covered was 254 miles and, as the folde
tells the story, it was accomplished "twixt daw
and dark."

New York Motor Fabric Co., Room 415, No. 3
Union Square, N. Y., have issued their first catalog o
fabric specialties for the automobile trade, and it i
a very commendable publication, containing 12 good
sized pages and a very neat cover. Their line of lam
covers, tire cases, etc., is very favorably presente
and nicely illustrated.

Rough Rider seat springs are both artistically an
practically advertised in a fine-looking booklet calle
"Automobile Comfort," and issued by Ventilated Cush
ion & Spring Co., Fisher Bldg., Chicago.

The Locomobile Company of America, whose fac
tory is located at Bridgeport, Conn., have issued thr
their publicity department, which is in charge o
J. A. Kingman, an inspection book for 1907 Loco
mobile Touring Cars. It is one of the most complet
and useful pieces of printed matter ever issued by a
automobile manufacturer, as it takes up the variou
difficulties or problems which confront the automo
bile operator and deals with them individually, intelli
gently and concisely.

It is a book 4½x7 inches in size and contains abou
ninety pages of text and illustrations. It has a tabl
of contents with classifications, so that as a referenc
book it is very accessible.

These instruction books are sent to owners of Loco
mobiles in such form as will command attention an
demand preservation. They are enclosed in a leathe
wallet which has a pocket on the opposite side, whic
can be used for maps and other data useful to th
automobilist. If more manufacturers would conside
the practical side of the automobile and endeavor t
fully enlighten their patrons it would be of great bene
fit, for such instruction books as the one referred t
cannot help but appeal in all aspects to the exper
enced automobilist as well as the novice.

Save 27 Minutes

The usual time required to replace a punctured tire is 30 minutes. With the

CRESCENT Removable Rim

(Formerly Harburg)

a complete tire change is made in 3 minutes, by the watch.

The above sectional view shows the permanent beveled band, fitted to the wheel felloe, the adjustable rim holding any regular make of clincher tire, and the hinged clip, six of which are used to hold the rim in place.

Extra tires and rims are always carried—the tire being inflated at home before starting on a trip.

When a puncture is experienced, the damaged tire with its rim is removed and the extra rim and inflated tire is quickly bolted to the wheel, the entire operation consuming but three minutes.

Nothing could be more simple. Irritating delays are absolutely done away with. All parts are galvanized, nickeled or bronzed, thereby preventing any possibility of their rusting tight.

Dealers' Department

Goods That are well Advertised - A Dealer's Ideas

The importance to the dealer of handling well-advertised goods is a factor that bright business men and automobile dealers and garage men have been quick to avail themselves of and have thereby enhanced their reputation and the value of their advertising inestimably. The corners of the road to success are rounded and the road is shorter and more smooth when this plan is adhered to.

The constant association of your name with goods of national or world-wide fame adds prestige to your standing as a dealer and likewise equips you to do better and more satisfactory advertising, while it brings immeasurably better results at less expense.

The small and comparatively unknown dealer who selects an unknown car or tire or other accessory of little or no reputation, even though of much more real merit, is, to say the least, handicapping himself very largely. He cannot give it more than a local reputation even though he puts much money and effort into its exploitation. And the weight of his well-meant assurances is largely dissipated thru the the public's lack of confidence in his recommendation.

It is comparatively easy to focus the attention of the public on an article or car of well-known manufacture and quality and one that the manufacturer himself has established the reputation of at an expense of thousands of dollars. The dealer has to establish his own reputation before he can attain to any considerable measure of success and as it is a very generally recognized principle that the best known goods are to be found in the most progressive stores, he should immediately avail himself of the first opportunity to annex such well-known and widely advertised goods as will enhance his standing and prestige.

Many dealers who have secured the advantages as outlined above have been far from successful principally from the fact that thro their inability to grasp the situation, or their improvident, slipshod or slothful methods of conducting their business, coupled with untidy or unkempt surroundings, they have been unable to obtain or retain all of the business that came to them. A glaring example of this class of dealer was our late friend the bicycle agent and repairman and as many of our present automobile dealers and garage men are graduates from the better class of these, let us hope that they have learned their lesson well and taken it to heart. Here was a splendid business that was boosted to the top notch of success through persistent advertising and then all but ruined through a ruinous and unbusiness-like competition. The manufacturers of first-class goods could not stay the hand of the jobbers of the "cheap and nasty" whose goods soon found their level and were handled by those of their own ilk.

The lessons taught by the bicycle are many and the fact that anyone in any old place could sell them, brings home to the dealer the importance of handling well-advertised articles and to both the maker and the dealer, the importance of advertising.

For the good of the business and all concerned let us hope that the manufacturer will take under advisement rather more than the mere ability to pay the price, when considering the placing of an agency: The location, environment, and calibre of the individual's character should be considered together with his facilities for the proper representation of a line of cars.

It needs no argument to convince the most skeptical that the automobile and commercial truck business is rapidly approaching a boom season and this not alone from the general excellence and utility of the vehicles, but from the fact that the manufacturers and all concerned are unitedly working along the same lines that at one time made the bicycle the most talked about and best advertised article of the day. Big money is spent on the racing game or touring contest and much more in giving these events publicity. This appeals to the popular idea of the masses and is good general advertising in which all classes of periodicals, gratuitously or otherwise, assist in spreading the gospel of the horseless vehicle. The effect on the public of the combined advertising of the maker, the user and the dealer, coupled with that derived from the great touring and racing events, is to unconsciously arouse an interest in automobiles and a little later comes a desire to know about the different kinds. Then the announcements of each company perform their special function and later on, those of the dealer also.

As regards the dealers who would be successful, the question of advertising has been positively and permanently settled for them in the affirmative; and it only remains for them to decide on how and when and what the advertising shall consist of. Shall it be the new and bright and logical kind with plenty of attractiveness for catching the eye, or shall it be the dull and commonplace announcements such as grandfather used?

The advent of the automobile has been productive of considerable prejudice which in

ADDRESS DEPARTMENT 4

AUTO IMPROVEMENT COMPANY

Hosted by Google

turn has created some adverse criticism; and while this criticism is unavoidable and in a measure regretable, it does, however, serve the purpose of general advertising even though it be of somewhat doubtful value. The widespread popularity of the automobile is, however, proving an irresistible power in breaking down prejudice and building up in its place a demand for the vehicles. No amount of "knocking" or adverse criticism can more than temporarily stay the progress of an article that has merit; and especially is this true of vehicles for the rapid transportation of persons or merchandise. This is progress that knows no restraining hand until the limit of possibilities along this line has been reached. The field is a large one that offers great possibilities to all who can measure up to the requirements.

The up-to-date advertising of to-day, as exemplified in the many exclusive automobile papers and the leading magazines, represents all that art can offer and money can buy at the present time and no more fitting object could be selected than the automobile on which to expend so much money or concentrated effort in high-class advertising. Handling well-advertised goods and catering to a good class of trade is usually a satisfactory and remunerative business in the long run and one that enhances the reputation of a house. Selling the "just as good" kind or the "cheap and nasty" will also prove efficacious in giving one a reputation, but it will be on a par with the goods and the conduct of the house. A MAINE DEALER.

[If you have ideas on this or kindred subjects in connection with the dealer's end of the business let us hear from you. The Cycle and Automobile Trade Journal is always pleased to further an interchange of helpful ideas.—Ed.].

Philadelphia Branch of the Mercedes Import Co.

The Mercedes Import Company, of 590 5th avenue, New York, has branches at Chicago, Pittsburg, Newport and Philadelphia. This last branch is at 153 North Broad street, in charge of Mr. H. B. Stillman, who has been connected with the selling of first-class cars for the last four years.

To begin with, the Mercedes agent takes high ground, asserting that the Mercedes is the best car, barring none; as it should be, since it is the highest-priced in all of its various models. The Mercedes now builds four different chassis models, of different powers and prices—35-H. P., $8400; 45-H. P., $10,150; 70-H. P., $14,000; all three of these having 4-cylinder motors and a 75-H. P., 6-cylinders, a nominal 1908 model, a few of which will be supplied this season at $15.000 each, for the chassis only, no bodies being included in the prices. The most ordinary equipment is a 7-passenger tonneau, cape top, body and lamps, costing about $1800 in addition to the price of the chassis. The prices of Mercedes bodies go up to $6000, when made to include pretty much every suggestion of convenience and luxury which can be included in carriage construction.

"The best in the world," thus becomes the keynote of the Mercedes selling talk. This is, of course, a very powerful argument. But this alone is not enough. However, a strong evidence of durability is given by citing examples of Mercedes cars which have been in almost uninterrupted use for 6, 8 or even 10 years, on American roads.

Little use is made of demonstrations on the road by Mr. Stillman, who does not always have even one car on view, tho it is the intention to have. Last year he had one car which he drove himself into the outlying residence districts in the early mornings and brought possible purchasers into town to business, either by appointment, or by studying the habits of his man and catching him between his residence and the railway station, a plan which had very good aggregate results.

Mr. Stillman thought he would do well to sell 10 cars the past year in Philadelphia, and it took two months to make his first sale, and another month to make the second one. After that the preliminary work began to show results, 50 cars being disposed of between April, 1906, and April, 1907, very nearly one-quarter of the total importation of Mercedes cars for the whole 12 months.

Mr. Stillman makes a great point of persistence and careful presentation to every possible purchaser, and says that the sales he is now making are without exception to men who have been under assiduous cultivation for from three to nine months.

Where a customer wants durability evidence Mr. Stillman shows his own 1902 Mercedes, 18-22 H. P., which has been driven hard for five years. This car has a heavy limousine body and has been driven without mercy from the first, with no repairs, it is claimed, of principal parts, save new babbitt bearings thruout, this car antedating the use of ball bearings in the Mercedes constructions.

The Boston Automobile Dealers' Association, at their last annual meeting, re-elected practically the old Board, as follows: President, J. H. MacAlman; vice-president, George H. Lowe; treasurer, Harry Fosdick; secretary, Chester I. Campbell; directors, J. S. Hathaway, A. F. Hinchcliffe, A. P. Underhill, S. K. Dingle, J. W. Maguire and Charles E. Ray.

An excellent example is set by the Union Electric Light & Power Company, of St. Louis, Mo., by which dealers generally could profit. This concern handles Studebaker and Rauch & Long electric cars, and to exploit the good points of these machines they issue a catalog quite as elaborate as many manufacturers' catalogs. This catalog possesses some unusual features, is well-illustrated and contains ample information regarding the cars and the facilities of the company for charging, repairing, etc.

The Githens Brothers' Company, Chicago. Oldsmobile and Stearns

HUGH DOLNAR.

The Githens Brothers' Company, 1328-30 Michigan avenue, Chicago, Ill., has the Stearns seven-passenger touring car, four cylinders, 60-H. P., price $4600.00, and the Stearns two-seated roadster, same chassis, at $4500.00, also the Oldsmobile, five-passenger touring car, four-cylinders, 40-H. P., price $2750.00, and the Oldsmobile three-passenger roadster at the same price.

Githens Brothers report sales up to expectation to May 1, then came a dull period, followed by better sales, tho not large, for the second week in June. Their 1907 trade, it is claimed, was nearly three times that of 1906.

The drop in sales May 1st, is believed by them to have been due to the cold weather, but, in spite of this, their 1907 May sales total was $13,000.00 in excess of the May, 1906, sales. They believe that even with a warm season from now on the 1907 sales total will fall far behind what it would have been with seasonable spring weather. Intending purchasers waited because of the cold, wet weather, and will not buy now because the outdoor time is so far gone.

This firm advertise once a week or more in the week-day papers and in the three principal Chicago dailies on Sundays. Two of the local evening papers are also used. The total advertising cost for 1906 was a shade less than 2 per cent. of sales total. A card is also carried steadily in two of the trade weeklies.

The Githens Brothers say that at least 90 per cent. of names to which sales are finally made come to them thru satisfied purchasers and friends. They had, at one time, no less than 55 sub-agents in three different States, Wisconsin, Illinois and Indiana. The last connection of this sort was terminated in the spring of 1907, because there was not enough to be divided. When they had 25 per cent. commissions they could give sub-agents 20 per cent., and make a living all round. When it came to 20 per cent. only, the commissions did not give enough. Again, the high-priced cars do not find a country market in large numbers. Their Milwaukee branch, established in December, 1903, was withdrawn January 1, 1907, and this company is now doing no business in the three States mentioned, outside of a radius of 150 miles from Chicago.

Names of possible buyers are kept in a card index file and communication is constant by personal interviews and by correspondence so long as a speedy sale seems probable. When a possible purchaser ceases to respond his name is placed on the "inactive" file, which is constantly studied, and is the subject of reminders from time to time, as seems expedient.

Form 2.—Githens Brothers' salesman's individual prospective buyer's name card, filled out and given to a salesman who is personally charged with attention to this particular customer.

When a sale is made careful and extended instruction is given, where needed, to either the purchaser or his driver, and in some instances to both; cars sold at prices up to $2750.00 are most often driven by their purchasers, but hardly ever is this true in the case of higher priced cars.

After a car has been delivered letters are sent once in thirty days, or the buyer is called up by telephone for a report.

Any fault of the car as sold is made good free of charge. The guarantee is for sixty days only. But a small list of repair components is carried in stock, and promptness in securing parts is secured thru telephone communication with the factory.

Trading in a second-hand car invariably means a loss for the sales agent, and the practice is followed from necessity only.

AGENT'S BETTERMENT.

Githens Brothers' suggestions for improvement of selling agents' business follow: First, the business habits and abilities of the agents themselves should be greatly improved. The business of selling motor cars does offer large opportunities for agreeable personal employment and social pleasure, but sound business qualifications on the part of the selling agent are an indispensable requirement. All promises and engagements must be made good, and promptness, energy and close financial management are necessary to win permanent success.

Second, manufacturers should be more careful in the selection of agents.

Makers of a new car are inclined to obtain sales by the use of new agents, which often results in placing an incompetent or irresponsible agent in new territory, which is the source of decided injury to the trade at large, since what hurts or discredits one car is bad for all cars.

Sound business principles alone can win success in trade, and the automobile is no exception to this trite rule.

Third, and specially emphasized by Mr. Githens, comes the imperative demand of a complete system of sales agency management, to be as rigidly followed as the production routine of any well-systematized factory. He points out that the sales agency of the motor car must include the function of repairer, both with replacements furnished by the factory and with hand work of thoroly competent and reliable workmen under the eye and authority of a skilled constructor, who can be depended upon for a rigid personal inspection of every repair job carried out at the agency work shop, and is also competent to select men suitable for sending to outside jobs, and to see that these men are assisted in every possible way for the protection of the interests of the customer and the reputation of the agency. He also enlarged upon the importance of satisfactory and able repairs foremen and repairs workmen and an efficient agency repair shop system.

The Githens Brothers have had a large manufacturing experience, and have carried a complete agents' repair shop system to success.

This system, which is the most complete of any so far noted by the writer, is the outcome of some years of improvement of originally well-devised form blanks, some of which are here shown and briefly described, and are worthy of careful study.

AGENTS' FORMS.

Besides the possible purchasers' names, office index and salesmen's cards shown in Forms 1 and 2, this company uses nine other principal form blanks, the customer's order to Githens Bros., numbered in duplicate with its carbon copy which is the repair shop production order, both signed by the customer, the original becoming the company's bill to the customer.

The agency stores room is supplied by requisition forms which are filled by the

storekeeper or by the repair shop superintendent and sent to the head of the department who acts as purchasing agent.

The stores room deliveries are recorded on another form, filled and signed by the stores keeper, and on still another form for the repair shop. Materials returned are credited on a special form, filled out and signed by the store keeper.

The workmen's time is charged on Form 3, time of work being indicated by a clock-controlled stamp. A repair shop envelope, printed in black, to take a complete record of each separate repair, is used and also serves to hold all related forms and papers,

R. W. Cook & Co., Chicago, Sales Agency for the "Royal Tourist"

HUGH DOLNAR.

R. W. Cook and Company, 1253-55 Michigan avenue, Chicago, handle the "Royal Tourist" touring car and roadster only. The 1907 Royal Tourist is a seven-passenger car, four cylinders, 5⅛x5½, 45-H. P., price $4000.00. The roadster has the same chassis, with seats for two passengers only, price $4000.00.

The Royal Tourist cars have been held strictly to prices named with no concessions. This company does not favor the trading of second-hand cars, but follows the practice to a limited extent.

Some advertising is done in the local daily papers, week-day and Sunday editions both, with no advertising in any other publications.

A large proportion of sales results from the performances of the Royal Tourist on the road, either by recommendations from satisfied purchasers, or from witnessing car performance.

A card index is kept of names of possible purchasers. No letter forms are used, each letter being suited to its recipient. The index card is a plain white blank, 3x5 inches, ruled red and blue, with no printing whatever. There is no settled routine for dealing with inquiries received by post or from callers.

After a car is sold close watch is kept of performance, inquiries are mailed once in 30 days to out-of-town purchasers and city sales are followed up by communications of drivers. Every fault reported receives immediate attention, commonly by workmen sent to the car. The Royal Tourist cars are sold with a guarantee for a year, and no repair charges are made in that time, save in case of accident or manifest fault of the driver.

For improvement in the condition of sales agents, Mr. Cook suggests refusing to trade in second-hand cars, and the closing of all manufacturer's branch houses entirely, everywhere, and selling thru agents only. The Royal Tourist has no branch houses.

Mr. Cook also says that 20 per cent. is not enough to pay for attractive quarters in a good locality, and pay for attentions purchasers should receive. His estimate of overhead expenses is at least 14 per cent. of the gross sales, leaving the agent 6 per cent. only.

Trading in of second-hand cars commonly results in a cash loss, and when there is an even money trade the agent loses the time needful to make the second-hand sale.

The Cornish-Friedberg Motor Car Co.

HUGH DOLNAR.

The Cornish-Friedberg Company, 1233 Michigan avenue, Chicago, are Chicago agents for the "Aerocar," 1907 models, which include a five-passenger touring car, water-cooled, 40-H. P., four-cylinder motor, price $2750.00; a four-passenger touring car driven by an air-cooled four-cylinder motor of 20-H. P., price $2000.00, and a three-seated roadster, same, 20-H. P., air-cooled motor, price $2000.00.

The Cornish-Friendberg Company has a factory at South Bend, Indiana, and began to make deliveries of its own "C—F" cars in March, 1907. The "C—F" line consists of a five-passenger touring car, driven by a water-cooled, four-cylinder motor, 40-H. P., and a three-seated roadster on the same touring car chassis, the price of either "C—F" model is $1750.00.

This company advertises in the local papers, both week day and Sunday editions, also in the suburban papers and in the trade journals. This company depends on local and suburban paper advertising for its agents' trade and looks to the trade journals for communication with possible sales agencies for its own "C—F" cars.

Names of possible purchasers are entered in an address book, not on index cards. If the inquirer resides in the city and does not call at the sales room in person, a man is sent at once to him, one outside salesman being employed. Out-of-town names receive an individual letter, no letter forms being used. If no reply is received the name is followed for two months or so before the matter is allowed to drop.

No time guarantee is given with cars sold, and no specified routine is followed after a sale is made, the assumption being that a purchaser's continued silence is evidence of satisfaction, and that no attention is needed until called for.

Great care is taken to fully instruct the purchaser, believing that this is the surest way to make a car satisfactory to the buyer, and that most troubles with cars come from ignorance.

Mr. Friedberg expressed the belief that agents could be very much benefited by exclusive territory alotments, and says that agents who sell the same car over the same territory are likely to cut prices.

The Cornish-Friedberg Company trade in old cars, altho declaring this practice to be bad, as forcing the agent to make two sales to obtain the profits from one.

The Ralph Temple Automobile Company

HUGH DOLNAR.

The Ralph Temple Company, 311 Michigan avenue, Chicago, Ill., is the Chicago selling agent of the "National" cars, of Indianapolis, and of the "Jackson" cars, built at Jackson, Michigan. In addition the company has a direct interest in the "Temple Tourist" and in the "Temple Marvel," the two latter cars being made in Detroit.

These specified motor cars furnish the company with ten different models of American cars, ranging in price from the "National" at $5000.00, to the "Marvel" at $850.00. All of these cars have four-cycle, water-cooled motors, and all but one are bevel-gear driven.

The Temple Company claims to be the oldest motor car selling concern in Chicago, and expects to sell from five to eight cars per day from February 1st to July 1st of the year, and actually did receive orders for eleven cars on the dav of this writing, June 13th.

Mr. Temple expressed the opinion that had the weather been good this season it would have been impossible to fill orders, and he also said that he believed the very backward season and the long-continued cold and wet weather would largely reduce the total volume of sales for this season and would certainly lead to a material reduction of prices for the season of 1908.

The Temple Company obtains the names of possible purchasers from commendations of satisfied previous purchasers in some part, from advertising in Chicago dailies, but more than from anything else from the personal efforts of six outside men, and from assiduous early and late attentions to callers at the Michigan avenue salesrooms. A considerable part of sales comes from replies to stranger enquirers, who have been favorably impressed by the performance of cars sold by the company, and by the close attention paid by this company to keeping purchasers' cars on the road.

Names once obtained go on a card index list, and letters go into vertical files in envelopes. No regular correspondence forms are used, all letters to enquirers being individual, and suited to personal conditions. Where correspondents do not reply promptly letters are continued at intervals. The only circulars sent out are regular descriptions of new cars.

The correspondence card file blanks are printed on both sides and are green or yellow in color, size 3x5 inches.

No name once placed on the Temple card file is ever allowed to drop, even tho years pass without an order. Car descriptions and personal letters are continued at interva', as past experience shows that any name n.ay develop into a purchaser, no matter how slow the enquirer may be in reaching a favorable conclusion.

Mr. Temple gives the following list of rules for selling agents, and believed to be indispensable to continued success:

First, any promise made by any one connected with the Temple Company to a customer is kept, no matter how much the subordinate may have exceeded his authority in making the promise. The fault of the subordinate is never permitted to disappoint the purchaser.

Second, in case a car sold develops faults which are clearly traceable to the factory these faults are made good to the customer by the Temple Company itself, which has had the purchaser's money and is the only principal known to the purchaser in the matter of the sale. If the Temple Company can recoup itself at the expense of the manufacturer, well and good, but in no case is the customer allowed to suffer.

Third, on notification of a customer's trouble a competent expert is sent immediately to the car, no matter how far away, and, except in case of repairs due to accident, no charge is made to the buyer.

Correspondence is continued with the purchaser after sale, and constant offers are made of assistance.

Mr. Temple's suggestions as to the general improvement of the selling agent's condition include better work and more cordial support by the manufacturers, and on the other hand better business methods on the part of the agents themselves, many of whom are good drivers and demonstrators, but are wholly deficient in commercial training, and do not live up to promises made to purchasers.

Mr. Temple also criticised the conduct of agency employees, who seek opportunities for outside money-making, often to the extent of actual theft.

Sound commercial principles and honest dealing are urgently required in the automobile business, the same as in every other form of buying and selling, if permanent success is to be obtained.

Mr. W. Wayne Davis, who has for some time past been connected with the Keystone Motor Car Co., of Philadelphia, has joined the Peerless force and will assume full charge of the Peerless department of the Quaker City Automobile Company, of Philadelphia, Pa.

At the last annual meeting of the New York Automobile Trade Association the following officers were elected for the ensuing year: President, Mr. Percy Owen, of Percy Owen, Incorporated; First Vice-President, Mr. Frank Eveland, of A. G. Spalding & Bro.; Second Vice-President, Mr. E. C. Partridge, of Wyckoff, Church & Partridge; Treasurer, Mr. William P. Kennedy, of Smith & Mabley; Secretary and General Manager, Mr. E. V. Stratton.

Commercial Motor Car Department

Experience of Commercial Motor Car Users

Wonderfully Successful in Shoe Delivery

The experience of the Chicago Quick Shoe Repairing Co., 120 James street, Syracuse, N. Y., shows that the automobile is the best means of delivering shoes. They use a Cadillac Model M delivery wagon, of 10 H. P., and state that it takes the place of four horses and wagons. The cost of operating the car they figure on a high average at about a dollar a day, excluding repairs. They carry an average weight of load of 200 pounds. The average daily mileage is from 15 to 20. The car cost them $950, and they figure it depreciates 10 to 15 per cent. per year. Cost of storage for car is $10 per month. They claim it better to store one's own car. Their car is driven by one of the firm.

They state that all machines should be made with vertical motors,considering the vertical motor more accessible and convenient for repairs or adjustments.

The automobile in this case not only insures quick delivery, but also is a great advertisement. They make no extra charge for collecting and delivering.

One Truck Replaces Four Wagons

Messrs. Kuntz & Johnson, Dayton, Ohio, are now using a Knox 24 H. P. gasoline truck for hauling purposes in place of four horses and wagons formerly employed.

With horses they hauled on an average of 1500 pounds per load, and made from four to five trips per day; one call per trip; covering two squares to three miles radius per day; their horses cost $175 each, and harness $15 per set.; average monthly cost of care and feed of each horse amounted to $16; shoeing $2.50; repairs to each vehicle $3.50; driver's wages each $40. They figure the horse to depreciate 1-3 and the wagon 15 per cent. in value in a year, respectively.

The truck has a carrying capacity of three tons, makes 30 miles on an average per day, in a two to five miles radius of territory. The truck cost $3000. Gasoline and lubricating oil are figured at $14 and $2.60 per month, respectively. Repairs and repair parts are figured at $10. The operator receives $60 per month. No helper is employed. Summing up the total cost of maintenance of the horse-drawn vehicle and motor car we find the horse vehicle expenses amount to a total of $248, as against $86.60 for the motor car, or a saving of $161.40 per month, or $1936.80 per year. They figure the motor to depreciate 1-3 in value in a year. They store their own car, which also helps to reduce expenses. No trouble has been experienced in securing a competent driver. Quick deliveries is the chief advantage of the motor car over the horse vehicle as suggested by their experience. They use 7-inch rubber tires on rear and 6-inch on front wheels, but claim they will not stand their use, and suggest that rubber tires should be done away with.

Wholesale Drug Houses Use Commercial Vehicles

The following is a brief account of the experiences of the Kauffman-Lattimer Drug Company, of Columbus, Ohio, with two 4-cylinder, air-cooled Frayer-Miller trucks.

The first was purchased in June, 1906, and had a capacity of two tons, and the second, of the same type, of 4 tons capacity, was put in service in March, 1907.

These trucks took the place of four wagons, one of which was a two-horse truck and the other three were single-horse trucks. The smaller wagons carried 2000 pounds, and the large one 5000 pounds, so the two gasoline trucks gave a carrying capacity of 5000 pounds more than the wagons. The trucks are run every day from 7 A. M. until 6 or 8 P. M., and are used for delivering to about 120 druggists and several manufacturers within a radius of 5 miles of the city.

The cars are kept at a public garage, for which a charge of $10 per month for each is made. The drivers are paid $17 per week and the helper $10, as against $10 to $12 per week for the horse drivers and $9 to $10 for their helpers. But with the motor trucks only two instead of four drivers are required.

The total expenses of the trucks, including drivers, from June 1, 1906, to January 1, 1907, were $657.64, and from January 1, 1907, to May 1, 1907, were $692.25. It will be noticed that the expenses were much lighter during the first period, and this is accounted for by the fact as stated by the company that during that period they had a very competent and careful driver, who

¶ Not an evolution from a pleasure vehicle, but designed strictly along truck lines with a surplus of strength in all parts.

¶ One man and a **Reliance Truck** will do the work of three men and three horse-drawn trucks, with an operating cost about equal to one horse-drawn truck. (We give you data and names of users to prove it.)

Write for catalog, and state kind of service in which you use trucks.
Some good territory open for responsible agents.

Hosted by Google

RELIANCE MOTOR CAR CO.

tended strictly to business and consequently the machine ran well and there were practically no repairs necessary. Another man was put on later, and as he drove carelessly and did not give the mechanism proper attention, there was continual trouble and much repairing and expense necessitated. The first man was then put on the large truck with the result that there was almost no trouble or expense with this machine. The company states it is now breaking in a good man for the old truck, and that soon it will equip a garage of its own.

In regard to depreciation, nothing definite could be obtained, the statement being made that this is the vital point and depends largely upon the care the machines receive and that their experience has not been long enough as yet to judge accurately.

The advantages of the motor trucks to this company are shown by the following statement: "We are to-day able to deliver 8000 pounds five miles from the store, together with two or three other stops to or from this point in one and a half hours, which formerly would take us a half day with a two-horse wagon. The two trucks, with reliable drivers, are very satisfactory."

Electric Truck Used by Brewer

According to the experience of the Gund Brewing Company, of La Crosse, Wis., the chief advantage in the use of electric trucks for delivering lies in the increased speed at which they can be run, thus effecting considerable saving in time.

This firm displaced a single and double-horse truck by an electric of about 1 ton capacity. Two trips per day are made, aggregating from 10 to 15 miles. The machine is not kept in an outside garage.

COMPARATIVE COST OF OPERATION.

The electric truck cost $2000, as against three horses at $225 each—$675; two wagons at about $675 each, making about the same initial cost for each equipment. The operating expenses average about as follows:

ELECTRIC TRUCK.		HORSE TRUCKS.	
Charging, per month	$10.00	Horse-feed and care	$9.00
Repairs, per month	11.00	Wagon Repairs	3.50
One driver	58.25	Shoeing of Horses	12.00
One helper	46.25	Two drivers	116.50
		One helper	43.75
Tot. per mo.	$125 50	Tot. per mo.	$184.75

The wages above are figured on the basis of 25 working days per month. The depreciation of both wagons and trucks are placed at about 10 per cent. The cost of harness and the renewal of batteries are not given, and would, of course, change these accounts considerably. The chief point for improvement is believed to be in connection with the storage battery, and the objection is made that it is sometimes impossible to negotiate roads which could be covered by the horse trucks.

Commercial Cars Used by the Boston Elevated Railway Company

The Boston Elevated Railway Company at the present time are using five gasoline cars, four of which are air-cooled Marions and the fifth is a Buick. Three of these machines took the place of eight horses formerly used with four business buggies. The cars are used by the department superintendents and foremen and are cared for on the premises of the company by one competent mechanic, who is paid a salary of $56 per month. With the motor cars an average daily distance of about 50 miles is covered as against 25 miles per day as a good average with the horses. The monthly cost of gasoline is $26.25 and lubricating oil comes to $2.63. The entire expense for the six winter months including repairs caused by accidents are: Labor, $62.05; materials, $41.01; shop charges, $15.22; total, $118.28. And if to this is added the cost of fuel and oil for six months, namely, $173.28, the total cost of operating the cars for six months is $291.56. In regard to depreciation the company states that it estimates it at 50 per cent. the first year and 20 per cent. on the depreciated value each year thereafter.

Truck Much More Speedy Than Horses

A Knox Model D-3 air cooled gasoline car is being used by a New England firm for hauling machinery. It is a 16 B. H. P. car and costs $2500.

They make an average of 14 short trips, covering 14 miles per day, in a radius of 1½ miles. Gasoline expense is figured at $12 per month and lubricating oil at $4.48. Repairs are figured at $87.58. They store their own car. The monthly wages of operator are $45, helper $35. They calculate that the car depreciates about 25 per cent. in value in a year.

They previously used one horse and wagon all the time and one horse and dump cart part of the time. The weight of load carried was slightly less than with the auto and the mileage was only about 10½ daily. Horses cost them $200 each; horse, wagon and harness $500; care and feed of each horse $11.20 per month; repairs to vehicle, $3. They state that the useful life of a horse extends over six years and value at end of period is $30. The useful life of a wagon is 8 years, terminal value $50. They have had no trouble in securing a competent driver. The most needed improvement to motor cars as suggested by their experience is reliability. They claim speed to be the only advantage of the motor car over the horse-drawn vehicle.

Only Cost Two-Thirds as Much as Horses

W. R. Kuhn & Co., East End, Pittsburg, Pa., have been using three electrics, manufactured by the Pittsburg Motor Vehicle Co., and one gasoline car, made by the Waltham Mfg. Co., for delivery purposes, and have found the motor car to entirely meet the requirements of their business.

The cars carry an average load of 700 lbs. and cost $1700 each. They make about six trips daily; twenty calls per day; covering about four miles radius of territory. They only received their gasoline cars a short time ago and therefore cannot give cost of maintenance, etc. The electric cars they charge with their own current and store themselves. They require no helper, only an operator to each car, who receives $10 per week. The cars have been in service for three years, and they claim they are running as well to-day as when new. The average monthly cost of repair work and repair parts is figured at $8.00.

Each car has taken the place of two horses and one wagon. The wagons have a carrying capacity of 12 to 14 hundred lbs. each. The load carried, trips made, etc., are the same as with the motor car. The wagons cost $475 each, horses $175 to $200 each; harness $35 per set. The average monthly cost of care and feed of each horse was $18.00, shoeing $3, repairs to vehicle $6, drivers' wages $10. They calculate the wagon to depreciate 20 per cent. in value in a year.

Mr. Kuhn in enumerating his experience states that the greatest trouble they have is in getting parts when wanted. They have been unfortunate enough to break an axle on two of their cars at different times and would have to wait three months for new parts from factory.

Mr. Kuhn considers the electric wagon, weighing 2200 pounds and carrying 700 to 1000 pounds, to be the best business proposition for a retail business, as the maintenance on a small wagon is so much less and it meets the requirements better than a large truck. Their tire renewals on three wagons in three years have only been about $150. They always carry an extra set of batteries, and have only removed two sets in three years.

In regard to maintenance Mr. Kuhn says: "I believe when seven to ten or more motor cars are required and they are charged at owner's barn with a careful man to look after them, they can be operated at half the cost of same number of horses and wagons, for it must be remembered that an electric wagon can run all day, where a horse must be relieved; in my business we use two horses in each single wagon; generally when we attempt to run them all day they soon go down. My experience with motor wagons for the past three years to me has been quite favorable and satisfactory. Some improvements have been made since on the same make of wagon we are using and the now should be even better."

A Farmer's Experience with an Automobile

Mr. Frank Brendle, of Salina, Kan., is using an 8-H. P. 1906 model Reo gasoline car for all kinds of purposes, hauling produce from the farms, salting stock, buying and selling cattle, etc. With his car he carries an average load of 400 pounds, and covers about 30 miles per day. The car cost $675.

Mr. Brendle has never had a breakdown, only a little ignition trouble once in a while. He has not kept account of fuel expenses, the only other outlay was for recharging batteries, one charge a year at the cost of $1.20. He stores his car in his barn, claiming it best, as no others can then meddle with it. The most needed improvement on motor cars, as suggested by his experience, is that of being careful. He runs the car on an average speed of 10 miles an hour when the roads are in fair condition. To fully meet his requirements he could use a little more power, especially when the roads are muddy or heavy. He claims the car to be as good today as when he bought it. Mr. Brendle also states that the average motor car is made too complicated and light for the rough usage in the hands of wild, reckless and inexperienced drivers.

Ships Fruit and Vegetables with Gasoline Truck

In the produce business Mr. Walter Waldin, of Miami, Fla., finds the motor car answers all the requirements of the business to his utmost satisfaction. He is using a one-ton gasoline truck, built by the Rapid Motor Vehicle Co., of Pontiac, Mich. Average daily mileage made with this truck is 28; two trips per day; 10 calls per trip; covering a radius of 7 miles. The car cost $1600. Monthly cost of gasoline and lubricating oil is figured at $15 and $3, respectively. Repairs are figured at $1 per month. He stores his own car. Wages are $9 per week for operator and helper. He figures the car depreciates $200 in value in a year.

Mr. Waldin states that his car has replaced four horses and two wagons, and that with the motor car he can make twice the number of trips and calls as with horses. As a suggestion he says that work could be saved if there were some substitute used for brass that needed no polishing. He also claims the motor car to save considerable time and that the horse vehicle has no advantage at all over the motor car. Mr. Waldin uses his machine when rushed as a power to pull an additional car carrying about 1500 pounds. In concluding his experience he states that his only trouble is that he cannot get a car strong enough which at the same time must be light, to stand 10 or 15 miles per hour.

The Soules 1907 Delivery Cars

HUGH DOLNAR.

The Soules Motor Car Company, W. F. V. Neumann, General Sales Agent, 736-40 Woodward avenue, Detroit, Michigan, U. S. A., is offering for the season of 1907 one delivery car, 1500 lbs., paying load, with the standard body, but is fitted with a variety of different bodies suited to service demands.

The first Soules cars were sold to purchasers in 1906. The motor of this first car was two horizontal opposed cylinders, set far forward under the hood, clutch-case and gear-case applied to the motor crankbox so as to form a rigid propulsion and transmission unit, all located in front of the driver's seat, where it is readily accessible by lifting the hood and the loose floor boards. The 1906 car cylinders were 4½x5 ins., nominal 15 H. P. In this first model the line shaft of the sliding gear speed change was splined; the drive was thru a universal shaft to bevel gears in the divided rear axle housing. The rear wheels were forced on the plain cylindrical axles and retained by key and pin.

For 1907 the Soules delivery cars have a larger motor, two cylinders opposed, 5½ x5 ins., nominal 22 H. P., the line shaft is squared instead of splined, and the rear wheels are forced on tapered axles, keyed and hex nut retained.

The same form of assembled motor unit is retained with the same far forward placing and the same ready accessibility.

As the power has been raised from 12 to 22 H. P., the 1907 Soules delivery car can do very much more work than the 1906 model, and can make good time thru deep sand with the full load. The construction of the change gear is much improved by squaring the line shaft, and the 1907 improvements greatly increase the working value of the car tho the price remains the same, $1800.00.

The pair of 5½x5-in. cylinders have more combined piston area than any other delivery car of the same rating, which makes the service quicker and better in every way.

The assembled motive unit has shown itself to be durable, and the location makes access and inspection very convenient.

The motor is nominal 22 H. P., and can easily show that on the road. The nominal paying load is 1500 lbs., but the power and tires are ample for 2000 lbs., and 2500 lbs. has often been carried on these cars.

The weight is about 2200 lbs. Price, $1800.00, with standard covered body, three oil lamps and full tool equipment, all ready for actual service.

Fig. 2. Soules 1907 Delivery car, change speed gear and clutch.

Commercial Vehicle Notes

A motor hose cart costing $2200 was placed in service in North Yakima, Wash., on June 1.

The Fire Department of Long Beach, Cal., have constructed their own self-propelled fire fighting apparatus. They removed the tonneau of a Rambler touring car and substituted a chemical apparatus on the rear deck.

Lee and Younghand are operating a electric omnibus service between Almont, Mich., and Romeo a distance of nine miles.

A motor hose wagon will be purchased for use in Winchester, Vt.

A motor stage is in operation between Picture Rocks and Montgomery, Pa., a distance of 20 miles.

Motor buses will replace the horse-drawn vehicles on the stage line of Nathaniel Church, operating between Tiverton and Seaconnet Point, Mass.

Motor cars were placed in service May 11 between Amarillo and Tucumcari, Texas, a distance of 115 miles is covered in seven or eight hours.

J. B. Van Sciver Company, of Camden, N. J., have purchased three Reliance trucks.

As a result of the enforcement of the "Jim Crow" law in San Antonio, Texas, the Texas Transportation Company has started a line of passenger motor cars patronized by negroes.

The city of Akron, Ohio, has ordered a Reo patrol wagon.

Motor cars now connect Kissimee, Orlando and Sanford, Florida.

The Merchants' Motor Delivery Company, Ft. Wayne, Ind., is the outcome of a move on the part of a number of merchants who absorbed the business of the Merchants' Parcel Delivery Company.

Postmaster of Pittsburg has been granted authority to procure the service of automobile for mail collection and delivery.

With a capital of $100,000 the Auto Transportation Company of Buffalo was recently incorporated to operate motor buses between the city line and Sheton Square along Delaware avenue and between the chief places in Erie, Niagara and Genesee counties.

"Reywat" Wins at Peoria

Out of the forty motor boats entered in the Webb Endurance Race of the Illinois Valley Yacht Club of Peoria, Ill., June 8, thirty-nine finished. The outcome is remarkable in many ways, showing the reliability and durability of the motorboats constructed to-day.

The race was held on the Illinois river over a 33.7 miles course.

The Reywat owned by H. L. and George A. Lawyer, of Peoria, Ill., won with elapsed time of 4.11.20, and S. and P. Stettman, and Potter (Chill), was second; time, 4.15.

Motor Boat Club of America

Spendthrift, after installing her proper batteries, won the motor boat race of the Motor Boat Club of America, on the Hudson River, June 29. The unfavorable conditions of wind and wave, rather than rain, deterred a number of owners from competing in the meet. Even with the delinquents the sport was first-class, and the club had the satisfaction of getting three splendid boats to start in the cruising race. The cruising boats come under class K, 40 feet and over, and each was a roomy, business-like craft, capable of making a long voyage if necessary. The three boats in class K were:

Alabama—Seventy feet over all, fitted with a 60-horse power American-British motor.

Mao II—Hull by Henry R. Gessner, 70 feet over all, 57 water-line, six cylinder, 60-horse power Lamb motor.

Kittu—Thirty-five feet over all, fitted with 25-horse power standard motor.

The competitors in racing boats not over 33 feet and not less than 26.25 feet in length class were:

Spendrift, owned by William Bjur, Jamaica Bay Yacht Club; boat is 30 feet over all, 29 feet water-line, fitted with a four-cylinder Rockaway motor.

May Be, owned by John W. Allison, of Elkins Park, Pa.; boat is fitted with a 40-horse power Leighton motor and is 35 feet on water-line.

The course used was identical in each class, once around representing 10¼ knots. The original plan was to have all the boats breeze around the course three times, a total distance of 30¾ sea miles. The cruisers were stopt at the end of the second round, however, and as the May Be ran out of gasoline she had to quit at the end of 20½ miles, and the Spendrift was the only racer to complete the demanded distance.

The racers were sent away at 3.20, and the cruising class was dispatched ten minutes later.

Summaries—Racers—May Be, did not finish; Spendrift, time 1.55.8. Cruisers—Alabama, time 1.41.30; Mao II, 1.43.33; Kittu, 2.01.03

Wolverine 2 and 4-Cycle Gasoline and Alcohol Motors

HUGH DOLNAR.

The Wolverine Motor Works, Grand Rapids, Michigan, U. S. A., make both 4-cycle and 2-cycle gas engines, using either two or three cylinders with either cycle, and producing motors of from 6 to 100-H. P., which are highly approved by users.

They recently received an order from Cuba for a launch motor, two vertical cylinders, 6½x7 inches, 4-cycle, to burn alcohol as fuel. This motor was shipt in April last, after a trial in the boat with gasoline, wood alcohol and grain alcohol as fuels, the cost of the alcohol being much the greater in the United States, but less in Cuba, where molasses is so cheap as to be burned as fuel under steam boilers, and can be made to produce alcohol at low rates.

The ignitor used by the Wolverine is make and break, wet battery and magneto, all ordinary elements, the magneto being by Remy and the batteries, six in number, by Gladstone and Ladande.

No change was made from the regular Wolverine 4-cycle construction, which is shown as a 3-cylinder 4-cycle motor in Fig. 1. The exhaust pipe, E, is surrounded for

Hosted by Google

Figure 1. The Wolverine 3-cylinder 4-cycle marine motor. The same cylinders and fuel supp used to make up the 2-cylinder alcohol burning motor sent to fill a Cuban order. No photogra taken of this alcohol burning motor, and no assembly drawing of it was ever made. E, exhaus J, Air-jacket around the exhaust, open to the atmosphere, thru which air is drawn downward air-pipe, A. A, carbureter air intake pipe, from the air-jacket J to the carbureter.

a certain distance by a jacket perforated to admit cold air, and piped downward to a mixing valve known as the "Wolverine Generator." This is of usual form, without float, and is partly shown in section in Fig. 2. The valve is held up against the piston suction by a light spring. The fluid fuel is admitted at F, and regulated by a needle valve at R. Air heated in the jacket, J, so that the pipe is uncomfortable to the hand, is drawn in by suction, presses the generator valve down and goes onward to the cylinder, carrying with it whatever fuel has been admitted to the valve chamber thru the regulating valve, while the air valve is held down by piston suction.

The whole fuel supply is of the simplest description, the fuel descending by gravity from the fuel tank and being stopt by the air-valve and its spring until the air valve is forced downward by piston suction.

Trial runs of about 50 miles total were made with gasoline and two kinds of alcohol, the motor being thought about 10 per cent. stronger with alcohol than with gasoline, because it turned the same screw faster, same boat and same motor.

The igniter shown assembled, and dissembled, in Fig. 3, is of usual form, platinum contacts. No photographs were taken of

The "Ideal" 1½ H. P. Marine Motor.

"Ideal" 1½ H. P. Marine Motor

To supply the wants of those desiring a motor of advanced design and high grade of construction and to sell at a price to meet the popular demand, the Tessmer Machine and Tool Co., 285 Rivard street, Detroit, Mich., offer the Ideal Motor herewith shown.

The cylinder is 3-inch bore and stroke. Ignition is by jump spark, timed by a reversible commutator. The crank shafts are hammer forged from a steel billet. The connecting rod is made of phosphor bronze, fitted with adjustable bearings. Two oil cups are provided for each cylinder, one of which lubricates the piston and piston pin and the other the crank pin and all internal moving parts. The speed of the motor is from 50 to 800 r. p. m. It weighs about 75 pounds complete.

"Junior" Marine Motors

The Chas. Crouch Motor Co., 474-482 Carroll avenue, Chicago, Ill., are manufacturing "Junior" 2-cycle marine motors in 1¼, 2, 2½, 4 and 8 horse power sizes. The accompanying cut shows their 2½ H. P., double cylinder type. This type is suitable for a boat 16 to 18 feet in length. The cylinders are 2¾-inch bore by 2½-inch stroke. The diameter of fly wheel is 12 inches. The

cal supplies are furnished for $21 and water fittings for $6 extra. This ty motor in 4 H. P. size is suitable for 18 to 22 feet in length, and lists at $1

Besides the 4 H. P. double cylinder, also make a 4 H. P. single cylinder m which lists at $119.40 with complete r accessories.

The Junior, 1¼ H. P., single cyl motor is especially adapted for conve

lo" Slow Speed Marine Motors

Buffalo Gasoline Motor Co., 1280-

after being machined up, is ground to size. The rings are made of hard, springy metal and are ground.

The connecting rods are steel drop forgings and are very strong. The crank pin ends, or journals, are made of a special bronze metal that they have tried out and proven on their regular launch engine. The piston end is bushed with bronze and has an adjustment so that any wear may be taken up.

The crank shaft is made of high grade carbon steel and of such size as to withstand hard usage.

The cams are of the best steel and are keyed on their shaft so that if one is removed it can be replaced without interfering with the timing.

Special attention is called to the base, which is a closed one, keeping the oil from

Buffalo Slow Speed Marine Motor.

getting into the boat. It is also provided with exceptionally wide bearings for the crank shaft. When a reverse gear is desired, a different base is put on. This base is the same as the former with regard to bearings, etc., but has an extension on which the reverse gear is mounted, and it also forms a thrust for the motor. In this way, the crank shaft, reverse gear and thrust bearings are sure to be in perfect alignment and the thrust is taken from the crank shaft.

The cams are all made of high-grade steel and are keyed to the cam shaft with Woodruff keys. The cam shaft is a ground steel shaft and can be taken from the machine without removing either the time gear or the valve cams.

The Wood End Life Saving Station, of Provincetown, Mass., has been equipt with a 25-horse-power motor lifeboat, measuring 34 feet in length.

The Duluth Boat Club, of Duluth, Minn., will have a new clubhouse on the St.

For Cleaning Auto Bodies

It's good to see how quickly Mobo removes mud, grease and dirt from an automobile body. It doesn't matter how long the car has gone without cleaning, or how thick the dirt may be—off it comes, easily and quickly if you use

MOBO

Automobile Cleanser

Not only does it remove all the dirt, but does it without marring or scratching the varnished surface, and without dimming the lustre in any way. That's Mobo style.

Mobo is composed of pure vegetable oils, and contains nothing rough to mark the smoothest surface. It is the ideal automobile cleanser.

Prevents the varnish and paint from cracking and blistering. Keeps the car looking new. It's the best sold to-day. Try it once and you'll understand why.

Put up in 3 lb. and 6 lb. cans; also in tubs, half-barrels and barrels. Can be had at the following supply house:

Belcher & Loomis Hardware Co.
89 Weybassett Street
Providence, R. I.

and at all good automobile supply stores in all leading cities.

Send for our Mobo booklet —"*How to Clean Well Varnish*

We print on this page each month an exact statement of the number of copies printed and distributed of the preceding issue of "The Cycle and Automobile Trade Journal."

The bindery count of actual complete copies produced of the August issue was 20,058.

Of these, 25,219 pounds were mailed at pound rates, as shown by post office receipts. Each copy weighs 21 ounces, representing 19,214 copies, and 4709 copies of back numbers and copies returned by news companies are accounted for, in addition to the total for the month.

We will be pleased to verify the above figures at any time to any one interested.

Pope Co. Slightly Embarassed

Pope Mfg. Co., of Hartford, Conn., and its various subsidiary companies, having been temporarily embarrassed by the inability to raise ready cash to meet loans that were falling due, has been placed in the hands of a receiver. The company, according to the receiver's counsel, is entirely solvent, having assets of $10,750,000 and liabilities of only $2,900,000.

R. H. Johnson has forwarded his resignation as treasurer of the New York Motor Club to President S. B. Stevens, Jr.

Coming Events

Aug 1, Sept. 30.—Amsterdam, Holland, International Exhibition of Motors and Machines, Palace of Industry.

September 1.—Italy, Brescia Circuit, Florio Cup, A. C., of Italy.

September 2—Overland Park Track Meet, Denver, Col.

September 2—Harrisburg, Pa., Race Meet of Motor Club of Harrisburg (probably Middletown track. Sept. 2, Chicago, Harlem rack, Race Meet under the auspices of the Chicago Automobile Club. Sept. 2, Bridgeport, Conn., Labor Day Hill Climb, Sport Hill, Bridgeport Automobile Club.

September 4.—Padova Bovolenta, Automobile Club of Venice.

September 5.—Cedar Lake Economy Run, Chicago Motor Club and Chicago Auto Trade Association.

September 7.—Minneapolis, Minn., State Fair Race Meet of the Minnesota State Automobile Association.

September 7.—Hartford, Conn., Hill Climb, under the auspices of the Automobile Club of Hartford.

September 9—Commercial Vehicle Trials of English Royal A. C.

September 14.—95-mile road race, Albany Automobile Club of Albany, N. Y.

September 14.—Jamestown (Va.) Exposition, Aeroplane Contest for "Scientific American" prize.

September 14.—Reliability Tour, under the direction of the St. Louis Automobile Club.

September 14-15.—Mont Ventoux Hill Climb.

September 15.—Semmering Hill Climb.

September 20.—Milwaukee, Wis., State Fair Grounds track, Race Meet, Milwaukee Automobile Club and Milwaukee Dealers' Association.

September 28-October 7.—International Automobile Show, Copenhagen, Denmark.

October 1-15.—Contest of Electric Vehicles, Automobile Club of France.

October 6.—Cup of L'Auto Maisons-Laffitte.

October 13.—Kilometer Contest at Dourdan, under auspices of L'Auto.

October 20.—Gallion Hill Climb.

October 21.—St. Louis (Mo.), International Aerial Race for the Gordon-Bennett prize.

October 24-31.—Eighth Annual Automobile Show; A. C. A., Grand Central Palace, New York.

October 31-November 7.—A. L. A. M. Show, Madison Squaqre Garden, N. Y.

November 1-15.—France, Voiturette Contest near Paris.

November 11-23.—Olympia Motor Show, London.

November 12-December 1.—Paris Show, Grand Palais and Place Des Invalides, A. C. of F.

November 30-December 7.—Chicago National Automobile Show, S. A. Miles, Mgr., No. 7 E. 42d st., New York city.

December 14-21.—Local Show, St. Louis, Mo., Auto Manufacturers' and Dealers' Association.

December 28-January 4.—Importers' Salon, Madison Square Garden, New York City. C. R. Mabley, Sec. and Mgr.

May 16, 1908.—Sicily Targa Florio, Automobile Club of Italy.

July 14, 1908.—Paris to London, Aerial Race.

The Rochester Automobile Club is having signboards erected in the neighborhood of that city. The signs are of uniform size and shape, being made of enameled iron. They give the name of the road, the direction to the nearest town and the number of miles.

Mechanical and Automobile Engineers Meet at Buffalo

Mechanical Branch of the Association of Automobile Manufacturers held its session in Buffalo on Monday and Tuesday, July 29, 30, in conjunction with the Society of Automobile Engineers.

Steels and their quality were discussed at Monday morning's session at the Buffalo A. C. rooms. On Tuesday afternoon and evening the subject of magnetos was taken up. A paper, by Otto Heins, of the Bosch Co., showed the necessity of a closer relation between the car maker and magneto manufacturers. During the meeting at Buffalo there were luncheons and inspections of the Pierce and Thomas plants and a run to Niagara Falls.

Plan Suggested for Co-Operative Control of Automobile Events

The Trades and Contests Committee of the Importers' Automobile Salon, was appointed in June, 1907, for the purpose of studying the basis upon which the most sportsman-like automobile events are held, and to submit recommendations for a method of improving and if possible placing such contests in this country upon a scientific basis.

The following is the substance of the recommendations, a copy of which was sent to the A. M. C. M. A., the A. C. A. and the A. L. A. M.

1st. That events exclusively for either American or foreign cars be discouraged. 2d. That those in charge of all contests be automobile or mechanical engineers of recognized repute and also representatives of the associations interested in the industry, such as the A. L. A. M., A. M. C. M. A., I. A. S. and the A. C. A. 3d. That such associations appoint committees to confer together and revise existing methods of conducting automobile contests. 4th. That the true horse-power classification, as given by the formula adopted by the Automobile Club of Great Britain and Ireland, be used until some international standard is adopted.

The following classification is urged:

Class A, beginning with 60 H. P. and over. Class B, beginning with 50 H. P. to but not including 60 H. P. Class C, from 40 to but not including 50 H. P. Class D, from 30 H. P. to but not including 40. Class E, from 20 H. P. to but not including 30. Class F, from 10 H. P. to but not including 20. Class G, under 10 H. P.

CLASS 1, PISTON AREA UNDER 35 INCHES. 1st. Autocar, percentage 10.065. 2d. Autocar, percentage 13.505. 3d. Holsman, percentage 14.65.

CLASS 2, PISTON AREA 35 TO 50 INCHES. 1st. Buick, 8.11. 2d. Maxwell, 11.011. 3d. Reliable Dayton, 15.68.

CLASS 3, PISTON AREA 65 TO 90 INCHES. 1st. Moon, 8.513. 2d. Buick, 9.183. 3d. Haynes, 9.23. 4th. Autocar, 9.30. 5th. Corbin, 9.69. 6th. Mitchell, 10.254. 7th. Oldsmobile, 12.49. 8th. Pierce Racine, 13.076. 9th. Rambler, 16.173.

CLASS 5, PISTON AREA OVER 90 INCHES. 1st. Pierce Arrow, 8.07. 2d. Berliet, 8.68. 3d. Stearns, 8.796. 4th. Berliet, 10.62. 5th. Apperson, 11.134. 6th. Stearns, 11.50. 7th. Packard, 12.036. 8th. Haynes, 12.04. 9th. Stearns, 12.234. 10th. Rambler, 12.42. 11th. Apperson, 13.837.

These ratings are based upon the accompanying table, prepared by Mr. Worby Beaumont.

The usual formula for calculating horse power was used in calculating this table, viz.:

PLAN.

33,000X2

When P equals mean effective pressure of 90 lbs. per square inch.

L equals stroke of engine in feet.

A equals area of piston.

N equals revolutions per minute.

Horse Power Table—Cylinder Dimensions in Inches and Fractions.

Bore. in.	0	¼	½	¾	1	¼	½	¾	2
2	0.54	0.60	0.67	0.74	0.81	0.88	0.94	1.01	1.08

To use table: Take the bore of your motor from marginal or left-hand column, follow directly across to the column whose heading in fraction of inches added to the bore gives stroke. The figure at the intersection of this column and your bore column gives the horse power of one cylinder of that size at 750 revolutions, and the figure immediately below gives the horse power at 1000 revolutions, which is generally accepted for computing present day high-powered motors.

The table represents the calculated indicated power given by one cylinder. For multi-cylinder engines the power shown must be multiplied by the number of cylinders.

Day Returns to Licensed Fold

George H. Day is again back in the ranks of the A. L. A. M., actively participating in its direction. Mr. Day some time ago resigned from active duties on account of ill health, but following the resignation of Milton J. Budlong as president of the Electric Vehicle Company, he was appointed July 30 to fill the vacancy thus created in the Executive Committee of the Association of Licensed Automobile Manufacturers.

As an evidence of the ever-growing popularity of the automobile, Mr. Alfred Reeves, of the American Motor Car Manufacturing Association, says that the demand for space at the Grand Central Palace, New York, surpasses even the demands of last year.

Already in almost every instance manufacturers who exhibited last year are clamoring for larger space this year, and the coming show in October is destined to be the largest ever held in this country.

Twenty-Four-Hour Race Rules

The Racing Board of the A. A. A. has promulgated rules for the conduct of 24-hour automobile races. These rules were compiled in order that records might be properly established and to avoid arguments over scoring methods and other grounds for dispute:

The rules are as follows:

1.—Twenty-four-hour contests shall be open to stock cars only, and shall be divided into two classes: (A) Endurance, (B) Relay.

1-A.—In class A each entrant shall nominate but one car and not more than two drivers.

In class B each entrant shall nominate not more than two cars of the same make, horse power and model, and not more than three drivers.

2-A.—(Section 20 American Automobile Association Racing Rules). The designation "Stock Car" shall mean a vehicle completely described in the manufacturers' catalogue for the current or any preceding year, and one which is on sale and ready for delivery to buyers, or has been on sale and sold to buyers.

B.—Stript stock cars under this classification shall be cars conforming to the preceding section with all or any portion of the following equipment or parts removed or replaced:

Body, signal devices, lamps (except between sunset and sunrise), running boards or steps, fenders or mud guards, mufflers (exhaust must not be directed towards the ground), recording and light generating devices, tools, spare parts, repair kits, tires and tire holders, tops, wind shields or bonents.

Note.—In class B a stript car may have as its relieving car, one fully or partially equipt car of the same make, horse power and model. This does not mean that two stript cars with equipt cars as substitutes can be used, but that two cars, one or both stript, or one or both equipt may be used.

C.—Fuel or lubricating containers may be replaced by those of equal or greater capacity, located as desired.

D.—No substitution of cars shall be allowed in the event of accident or other reason, and the factory number of the motor and the manufacturer's serial number of the car shall be declared before the start.

3.—In class B cars of each entrant shall carry in the usual places the same entry number, preceded by the letters A and B respectively.

All competing cars shall carry suitable head and two tail lights between sunset and sunrise.

5.—Drivers may alternate and in case of accident to a driver or drivers, application must be made to the referee who may, in his discretion, give permission in writing to substitute another driver or drivers.

6.—In class B the two cars on any team may be interchanged at will, it being understood that when one car relieves another the retiring car must come to a full stop beside the relief car before the latter is started.

7.—In any event in which more than five cars are actually running on the track, all supplies must be taken on and repairs, replacements and adjustments made in the paddock, which shall be in charge of a paddock judge, appointed by the referee.

8.—Each race official shall have an assistant to act as a relief.

9.—It is recommended that a mechanical means of recording the score be used and that the score be posted at the end of each fifteen minutes in full view of the race officials and press.

Exports Soar Skyward

Government statistics show that there is a continued increase in the exports, June being $732,054, an increase of $192,786 over June, 1906, and $76,604 over May, 1907.

Exported to—	June 1906.	June 1907.
United Kingdom	$194,709	$310,632

Gasoline Machines Allowed on Piers

Thru the efforts of the American Motor Car Manufacturers' Association and the New York Automobile Trade Association the following steamship companies have signified their willingness to allow gasoline motor trucks on their piers, and a number of other companies have the matter under consideration. The Enterprise Steamship Company, the Brunswick Steamship Company, the Maine Steamship Company, the New York and Porto Rico Steamship Company, the United Fruit Company and the Ward Line.

Double Check System to be Used at Shows

At the eighth annual Automobile Show in Grand Central Palace, October 24-31, several new features will be introduced regarding tickets and badges, chief among which will be a double check system for exhibitors. Each exhibitor will receive a non-transferable admission badge and ticket for his own use and for each employe necessary for the proper conduct of his exhibit. The badge is not good for admission in itself, except when used in connection with the admission ticket. Upon leaving the building a ticket will be given to be used for admission on returning.

Our Special Show Numbers

On account of the early dates of the shows this year much costly delay will be avoided.

The first show will be held October 24-31 at the Grand Central Palace, New York, under the auspices of the Automobile Club of America and the American Motor Car Manufacturers' Association. Our October number will therefore be the first show number. The November issue will be the second show number and will contain a forecast and space distribution of the Association of Licensed Automobile Manufacturers' show in Madison Square Garden, October 31-November 7. The December number will be the Chicago show number, which show will be held November 30-December 7. In addition to these the January number will be the Great Eighth Annual Buyers' Guide Special. The February issue will be the Boston Show Number and the March edition the Eighth Annual Complete Vehicle Review.

Counsel for the Massachusetts State Automobile Association are preparing to test the constitutionality of the law which went into effect August 1 compelling owners of machines to pay a fee of $5 for each car instead of $2, which has for some years been required. Members of the Worcester Automobile Club are instigators of the test case, but they are being joined by members in other cities.

Philadelphia, September 1st, 1907

Cycle and Automobile Trade Journal Moves into New Plant

We are pleased to announce to the trade and our readers in general that we have removed from 1213 Filbert street, Philadelphia and are now installed in our new plant at Forty-ninth and Market streets, Philadelphia. The Trade Advertising and Publishing Company and the Chilton Printing Company, both under the same management, have now been consolidated and will be known as the Chilton Printing Company; James Artman, President; Geo. H. Buzby, Vice-President, and C. A. Musselman, Secretary and Treasurer.

With our now enlarged facilities and with the Editorial and Printing Departments under one roof, we hope, if possible, to make the Cycle and Automobile Trade Journal even more useful as a trade publication than in the past, and will take pleasure at any time in receiving and showing our friends thru our new quarters.

The Glidden Tour—An Impossible Combination

Unfortunately the promoters of the Glidden Tour do not yet seem to realize that they are laboring in vain to combine two incompatible events, a pleasure tour and as severe a test of automobiles as can well be imagined. Who will say that the recent tour was a pleasure event? It was as nerve-racking, weight-reducing and trying an ordeal as none but the most hardy could endure. To begin with, there are altogether too many entrants to constitute a pleasure tour even if the time schedule was not so strenuous as to cause even conservative drivers to take appalling chances. The persistency with which the idea of a pleasure tour is clung to, in spite of the fact that the event is in reality a strenuous contest, is ludicrous in the extreme. This persistency simply introduces rulings and prohibits others which would make the contest a true index of individual car superiority, for no one will deny that long hard tours over such roads as are to be found in this country do, as nothing else can, bring out the weak points of the cars. Made strictly a contest, divorced from the pleasure tour idea and conducted under rigid contest rules, much valuable information could be obtained and made public, which is manifestly impossible under the present conditions. Each car should have an official observer, tire troubles should not under any circumstances be counted against the score of a car, or if counted should be kept separately. But above all an accurate record should be made of each and every trouble encountered and at the end the cars should each be thoroly overhauled and critically examined by a representative body of automobile engineers who would then pass upon the condition of each part and by suitable penalization complete the score of each car. All records should be public property if the benefits possible from such a contest are to be derived.

Under such a ruling there would be no chance of heralding a car far and wide, as a perfect score machine, when in reality at the close of the tour it is fit only for the scrap heap while some sweet running piece of automobile mechanism as was ever made, thru tire and minor troubles has a blackened record which might lead one to believe it almost unfit for touring service.

There is no objection to a pleasure tour as such, but there is a decided objection to mixing up such an event with a contest and thus spoiling the pleasure to be derived from one and the knowledge and benefit to the industry which might be derived from the other.

In certain quarters we read that the tour is useless and shows nothing, proves nothing. With this we certainly do not agree as we believe much information was obtained, even under the present arrangement, but are firmly convinced that much more useful information to the manufacturer and the public, can be obtained if the tour is made entirely competitive. Everything is not yet known concerning automobile construction, and such a road event can be made extremely valuable, particularly as it deals with stock models on average American

Hosted by Google

roads. We heartily indorse the promotion of all such stock car contests, but let them be under the supervision of engineers, entirely distinct from pleasure events and by all means allow all the results to be made public.

Questionable Advertising Methods

Some automobile manufacturers and dealers are shortsighted enough to employ advertising which, altho not absolutely false, at least gives an entirely erroneous impression to the reading public. Such practices are to be condemned and sooner or later the deception is found out and undoubtedly works injury to the dealer or firm employing these methods.

The type of petty deceit referred to was shown in several advertisements which appeared in the daily papers following some of the recent endurance contests in which the order of the finish under the rules of the competition, meant absolutely nothing in regard to the merits or demerits of the cars. Yet the advertisements in question blazened the fact that such a car finished *first,* thus giving the readers a false impression as to the results of the contest.

In many instances the winners of certain events are specially built cars entirely different from the same make of car as known to the purchasing public; yet the fact that these cars are specials and perhaps no more like stock models than a Vanderbilt racer is like a buckboard, is carefully concealed in the brazen advertisements which intentionally or otherwise make it appear that the winning car was of the regular type. In one particular instance a maker mounted a regular 4-cylinder motor on two sills and used light wire wheels. There was practically nothing used but the motor that ever entered into the regular stock model construction. This freak won a hill climb and it was immediately advertised far and wide that that particualr make of car won. No mention whatever was made of the true state of the case, and the deluded purchaser was made to believe that that particular make of car was a great hill-climber. In some cases cars are specially tried out on a certain hill upon which there is to be a contest and the gear ratios changed until one is found to suit that particular hill. It makes no difference whether the rules of the contest admit of such a practice or not, in regard to the questionableness of advertising such a car as the winner when nothing whatever is said about the questionable methods used to obtain the result.

In still another instance a dealer spread by means of glowing advertisements the fact that his make of car was awarded a gold medal at a certain exhibition, giving the impression that this was for excellence of design when in reality the award was given for a booth decoration or something equally irrelevant to perfection in motor car construction.

Such deceptive practices in advertising may delude a few, but sooner or later when the truth is known, cause a very depreciatory view to be taken of all future claims made by that individual or firm and may even start a public decline of confidence in that make of car, and we cannot too strongly point out the fallacy of such questionable advertising methods.

Fallacies in Testing Shock Eliminators

Since the introduction of the various types of shock absorbers there have been several methods employed by different manufacturers and others to make scientific tests which would show graphically the advantages claimed for their various devices when applied to an automobile. In every instance that has come under the notice of the writer, the method employed consisted in obtaining a curve, the abscissa of which was time, and the ordinates the motion above or below a medial line, of the body relative to the axle.

But does a curve with shorter ordinates when the device is applied, than the curve obtained without the use of the shock absorber, prove conclusively that the car is made easier riding by the shock-eliminating device used? The writer is of the opinion that it has very little bearing on the subject. In the first place easy riding cars are not necessarily shown by lack of relative motion between the body and the axles, for if this were the case, a car in which the body rested rigidly upon the axles, without any spring being interposed, would give a perfect curve which would be of course a horizontal line. Furthermore, it is very possible for a car to be easy riding in which there is a large relative motion between the body and the axles, provided, however, this motion covers considerable space of time, or in other words, whose vibration is a slow one, altho its amplitude may be large. Curves made in the usual way, in which the portions of the curve representing a change of motion from upward to downward, or vice versa, are not sharp, but very gradually rounded, would indicate to a certain extent, easy riding cars, as such a curve would show that the body was not suddenly thrown upward or deprest, but that such motions covered a considerable period of time, and could be compared more accurately to the rising and falling of a boat, than to the jolting of a wagon body. From these facts it will be seen that the amount of vertical motion between the body and the axle, may mean very little in regard to easy riding qualities, but that the time of vibration means everything, when smoothness of action and lack of jolting is the question under consideration.

There seems to be but one true indication of the riding qualities of a car, and that is

Hosted by Google

the varying pressure of the weight of an individual or occupant of the car upon the seat cushions. If a curve of such pressure variations upon the seat could be obtained, this would indicate conclusively whether or not the occupants would be thrown violently into the air at one moment, and suddenly met by the rising car at the next. The point in the curve which indicated that there was no pressure on the seat would show that either the person had been thrown upward from the seat or the car had dropt from under them. If this were followed by a sudden rise in pressure, it would indicate the landing heavily of the person upon the seat, or in other words, a curve of the variation of pressure of the weight of a person or of a load equivalent in weight, would be an accurate indication of the riding qualities.

Altho difficulties might be met in devising a pressure-recording instrument which could be placed upon the seat, and either a dead weight equivalent to that of an average person placed upon it or could actually be sat upon by an occupant of the car, such difficulties could easily be overcome. With such an instrument records could be made in competitive tests of the different shock-eliminating devices on the market and with such a curve as a basis of comparison the relative merits of different instruments could be determined. Scientific tests of the minor details of automobiles will in time be made, but at present, the American makers are too interested apparently in the main features of the mechanism to take the necessary time and expense to demonstrate such minor features. Nevertheless, such scientific competitions would be very enlightening to the purchasing public, and would also form the basis of very advantageous advertising. We look forward to the time when every part of the American automobile will be submitted to competitive tests under the supervision of competent engineers.

Electric Transmission

Elsewhere in this issue of the Journal the first plain and fairly complete story of electrical transmission is given to our readers.

The electrical transmission is the work of Justus B. Entz, a very able electrician who is thoroly familiar with the storage battery, having been the Chief Electrical Engineer of a very large storage battery factory. It is highly significant that Mr. Entz, who has had an extended experience in directing some very large ambitious and costly applications of the storage battery to vehicles of various classes, including street railway cars and commercial work, should now be giving his attention to motor car driving by a gas-engine with electrical transmission between the engine and the driving wheels, thus abandoning the use of the storage battery and at the same time doing away with all forms of toothed gearing for speed changes. This arrangement also supplies electrical brakes, which effectually control the movements of the car.

The Mercedes is placing the same combination in 1908 cars, a gas-engine with electrical transmission.

The great advantage of electrical transmission is its simplicity, and its possibility of giving varied effects without the use of separate machine parts.

The Entz transmission gives 5 forward and two backward speeds, also an ordinary brake effect and a "sprag" or hold-back effect in both directions, making it impossible for a car to coast down hill either forward or backward at a speed exceeding about two miles an hour, all without any gears of brakes or ratchets and pawls whatever, simply by moving a small controller handle which requires only the slightest muscular exertion on the part of the driver. Mechanical brakes are, of course, provided so as to give the driver control if the electrical system fails.

It is well known that really satisfactory brakes are few, and 1908 practice is divided between metal to metal and fibrous facing. Electrical brakes do not require contact of surfaces, and hence cannot give rise to mechanical wear.

The story of electrical transmission to which attention is called is not only the first ever printed showing the possibilities of this form of car control, but is told in such plain language that readers having very little knowledge of electricity can understand what can be gained.

The Entz system involves a broad new invention, and not only produces many highly desirable effects not shown in the Mercedes system, but is vastly more economical of engine power, so that American gas-engine driven cars employing electrical transmission need fear nothing from comparison with the Mercedes.

The work of an American, Stewart Perry, 1842-46, anticipated that of Lenoir and Daimler by many years, and it now seems to the writer that Perry's 2-cycle gas-engines and the Entz Electrical Transmission will make the final motor a wholly American production.

Growing Demand For American Runabouts

It seems surprising that neither France nor England has appreciated the value of meeting the demand for medium-priced machines. They have devoted their energies almost exclusively to manufacturing the most expensive type of cars, and for this reason it is not surprising that England has turned to America to meet this want. There is a great field abroad for runabouts, and English makers are beginning to wake up to this fact and are preparing to supply this demand. While few, if any, of the expensive American cars are exported, statistics show that there is a general increase in the number of American runabouts exported.

ne statement received from the secre-
s office of the American Automobile As-
tion.

is decision was reached by Wm. K.
lerbilt, Jr,. and chairman of the com-
on Mr. Jefferson De Mont Thompson,
being in correspondence with the act-
hairman by cable.

e deferring of the race this year was
ed wise in view of the many delays and
the following specific reasons:

e unfavorable attitude of the Governor
ne State of New York with regard to
proposed use of the militia to guard the
se; the failure of the New Jersey State
te to convene in special session owing
ead-lock; the great distance which the
gners would be obliged to travel in the
t of accepting the very cordial invita-
of the Governor of California, and the
of assurance from Missouri, due to the
nce of Governor Folk from the State,
the guard of that State could be used.

White Wins Hower Trophy for Runabouts

order to decide the owner of the Hower
ny, it was necessary that the two cars
for the trophy should travel 2080 miles.
White car, driven by H. K. Sheridan,
the Stoddard-Dayton, by G. S. Smith,
ed on Monday, July 29, on the sup-
entary contest to continue from day to
until one was penalized. The contest
run under the rules governing the Glid-
tour with the important additional re-
ement, that an observer be carried on
car. The contest lasted three days, the
day the cars ran to Albany; 155 miles,
car was the only car to arrive on schedul
time.

The cause for the delay of the Stoddard
Dayton car is well explained. On Wednes
day, when the contestants left Syracuse, th
Stoddard car was suffering from a broke
spring, which had been repaired as well a
possible without penalization. Fifteen mile
out from Syracuse the spring snapped an
was patched up without new materials an
the car hobbled along to regain lost time
At Batavia the car met a fireman's parad
and, it is claimed, lost its way in trying t
avoid it.

Long Distance Race Being Planned for Ormond

How about the 1908 Ormond Beach races
This is the question now being frequentl
asked because the Vanderbilt race canno
be run. The shows will be thru early an
American makers have racing cars finishe
and also an anxiety to try them out. Th
promoters of Ormond are thinking deepl
and planning, and the A. A. A. Racin
Board is more than anxious to aid them t
make the event of next year the greates
ever known on Ormond Beach. It seem
quite probable that a long distance rac
will be put on to replace the Vanderbil
contest and that loops will be constructe
on the beach and land so that the cars ma
run continuously for any distance require
With this done it is probable Europea
makers will send their fastest cars to thi
country. The proposed long distance strip
ped touring car race may also be conteste
there. It is said now that the long race
will be put on first with time limits insid

Digitized by Google

red or be forced to run in a class by themselves. At any rate there is every chance that Ormond will be a greater meet than ever in 1908.

Brighton Beach 24-Hour Race

A new one-car record was made in the much-heralded 24-hour race on Brighton Beach Track, under the new A. A. A. rules, August 9 and 10, by Montague Roberts driving Harry S. Haupt's 60-H. P. Thomas Flyer. He did 997 miles in the 24 hours.

The winning Thomas being viewed by the crowd at the 24-hour races at Brighton Beach, L. I. This car made a new one-car record of 997 miles.

He was stopt no less than four times to light his tail lamps, and at one time it looked as tho the question of lights would decide the race. A 40-H. P. Lozier car was second, with 972 miles to its credit, and a 40-H. P. Jackson third, having covered 966 miles. Altho 15 cars had started in the race, only six were participating when the time limit was reached. A 35-H. P. Mitchell was still going and had 774 to its

racq, with a score of 774 miles, and a haye, with 720 miles, were undergoin justments when time was called. The F Miller held the lead continuously up t sixth hour, when it skidded thru fence, damaging the car so badly that i withdrawn. The table following give scores of the 15 starters and the numb hours they ran:

	Driver.	Hrs.
60 H. P. Thomas.....	Roberts	24
40 H. P. Lozier.....	Smelzer-Lynch	24
40 H. P. Jackson.....	Burman-Cobe	24
35 H. P. Mitchell.....	Zirbes-Hudson	24
45 H. P. Delahaye....	Mongini	24
50 H. P. Darracq.....	Nuneman-McCalla	24
35 H. P. Oldsmobile...	Sturwood-Anderson	18
50 H. P. Welch.....	Trewin-Greenwood	18
50 H. P. Matheson....	Ryall	17
50 H. P. De Dietrich..	Fuller	9
.. H. P. Frayer-Miller	Lawwell-Knepper.	6
35 H. P. Oldsmobile...	Michener-Mufford.	..
28 H. P. Pilain.....	Strang	9
40 H. P. Lozier.....	Howard-Thomason	13
35 H. P. Stoddard-D..	L. and J. Light...	17

Preceding the 24-hour race several and middle-distance races were run. W Christie, in the front drive racer whi built for the French Grand Prix, furn the fastest burst of speed on the Bri Beach track by doing the mile in 5 seconds, thereby wiping out Barney field's time of 1.00 2-5, which had stoo two years. It was the first occasio American public had had of witn Christie's new machine at work. The cipal event was the 100-mile Brighton middle distance Derby. There were starters. Vaughn, driving a Stearns, the lead up to the 45th mile, when a b gasoline connection caused a stop fo pairs. After returning to the trac again got the lead, the second man, i meantime, having also retired for re and he held his place till the 82d mile,

Digitized by Google

The Thomas and Jackson on the turn, followed by the Delahaye and Oldsmobile. The Jackson Thomas closely contested for leading position, which was held by the Jackson until the 23d r, when an accident put the car out. The Thomas had continual tire trouble and was de- ed several times by the referee to light its tail lamps as per the new A. A. A. rules; but lly won, making 997 miles in the 24 hours.

oken chain again put him out of the est for a time. Elliott, on a Packard, back of Vaughn in the 19th mile, but his place in the 59th on account of trou- and when he returned was four miles nd Vaughn, with a Lozier, and Stude- r also ahead of him. At 90 miles he ed the Studebaker, but failed to catch o the Lozier, which finished in 2.06.21. tt's time was 2 hours 12 minutes.

e Atlantic City, N. J. Automobile Carnival

e Automobile Carnival, August 5 to during which there were three days of g on Ventnor Beach, a floral parade an automobile show, provided enter- nent for thousands of the mid-summer sure seekers at Atlantic City.

nly one record was broken and that was he big six Stevens-Duryea in the third t, a championship race for touring cars the Atlantic City Bureau of Information valued at $500. The six-cylinder car fully equipt and carried five adult pas- ers. The mile was covered in 1.06 3-5, h is 2 1-5 seconds better than the Eng- Daimler record of last year. Guy ghn and Church's Stearns were debarr- s they were classed by the judges as abouts, rather than touring cars. The re of the day, however, was the class regularly equipt gasoline runabouts. Of 14 entries only 6 started. The B. L. M. kept out as it was stript. Leland's six-cylinder Stearns won easily in 52 nds, with the Thomas "forty," driven McIlvred second, and Guy Vaughn in Stearns third.

e first race was won by T. W. Berger Oldsmobile and was the first of a

THE SECOND DAY.

The second day's races were the best o the meet, all being hotly contested wit several grandstand finishes. The event were run off promptly and some fast mile made, altho no records were broken. Th record for the day was made in the thir race, a free-for-all, which brought togethe such well-known cars as the 120 H. P Thomas Vanderbilt racer, the B. L. M. ca built for the Vanderbilt race, the Matheso Vanderbilt car, the six-cylinder Stearns an the Stevens-Duryea Big Six. Two heat were run and the winner of each and th fastest second car were chosen t compete in the final. The finish brought th Thomas, Stearns and Stevens Duryea to gether and the Thomas won in 40 2-5, s far the fastest time of the meet, the Stearn was 1 2-5 seconds behind. Christie's tim of 34 seconds still stands as a record, bu was not made in competition.

A PECULIAR ACCIDENT.

The only other event in which the mil was made under a minute was the speci race for stock touring cars against tim The six-cylinder Stearns of Leeland was th only starter and after covering the cours in 44 flat, just after passing the line th fly-wheel of the speeding car burst sendin part of the floor boards and the dash hig into the air and badly damaging the moto No one was injured but the car could no compete in the next day's races. There wer eight events in all and the slow time in sev eral is accounted for by the fact that the were handicap races and necessarily wer run from a standing start.

THE THIRD DAY.

Unfortunately the racing on the third da was not so good as the two previous day The cars were slow and the course in muc worse condition than before. Improvise races were run to fill in the gaps wher there were no starters. However the spe

Hosted by Google

The Stevens-Duryea Big Six which did the mile in 1.06 3-5 at Ventnor Beach, which is 2 seconds faster than the previous record for stock touring cars. The car was fully equipt carried five adult passengers.

FLORAL PARADE.

The floral parade turned out to be simply line-up of cars, as only three of the 36 ars in line were decorated. A Studebaker ar entered by Miss A. T. Nichols and ocupied by four ladies and a driver presented he best appearance.

THE AUTOMOBILE SHOW.

The three days' Automobile Show in the lancing hall on Young's New Million Dollar Pier, a show room with a clear floor space 50 by 250 feet, was well attended and prounced a decided success. The pier was eautifully decorated and there was a good epresentations of the well known cars altho f course the exhibits were not as representative as the mid-winter shows.

Reading Race Meet

The postponed race meet of the Reading Automobile Racing Association was held uly 26 on the half-mile track at the fair rounds. No fast time was made, as a light ain made the track too dangerous for fast riving. Pullman cars won four of the ight automobile races carded, and R-S motorcycles carried off the prizes in the two vents for motorcycles. Summaries:

Half-mile obstacle—Won by J. E. Sellers, Maxell. Time, 0.45.

Two miles for gasoline stock cars—Won by hester B. Smith, Jackson. Time, 3.01½.

Three miles for stript stock cars—First heat on by Robert Morton, Pullman. Time 4.42. Second heat won by J. A. Kline, Pullman. Time, 4.40.

Stock touring car gymkhana—Won by Robert Morton, Pullman.

Three miles for gasoline stock runabouts—First eat won by J. A. Kline, Pullman. Time, 4.37. econd heat won by Robert Morton, Pullman. ime, 4.41.

Three miles for gasoline stock touring cars—Won by William Haggerty, Acme. Time, 4.47.

Two-mile match—Won by Robert Morton, Pullman; second, W. E. Smith, Ford. Time, 3.26.

Milwaukee Hill Climb

Milwaukee Automobile Trade Association best performance of the day. Seven o eight events were on a price classific basis and one was a free-for-all for a tr donated by the Milwaukee Sentinel.

The first event for small cars was by a Ford runabout in 46 2-5 seconds, it bettered this time by one second in next small-car event. In Class 3, cars ing at $2000 and under, a 22-H. P. B won in 41 2-5 seconds. A 35-40-H Rambler won in Class 4, cars listing $3000 and under; time 35 2-5 seconds, w was the best time for four-passenger t ing cars. The same car and driver wen in 33 2-5 seconds in another event. A f cylinder Jackson went up in 30 4-5 in free-for-all and a Wayne did it in 32 1

Creditable Performance

The recent performance made by the more car driven in the Glidden tour by Becker is very noteworthy, and goe demonstrate the correctness of the two-c principle. The car entered by Mr. Be was a 35-horse power two-cycle Elm and previous to leaving Cleveland all p of the car were sealed, so that no rep or adjustments could be made without br ing a seal. He reached New York Cit the finish of the 1600-mile contest wit seals still intact. After the car finished contest it was turned over to the New Y agents, who ran it around New York, ering about 500 miles. The car was run to Philadelphia, where it was used Gawthrop and Wister, local agents for Elmore car, for demonstration purpo covering about 400 miles. The car shipt back to the factory with all seals intact, having traveled, it is claimed, i about 2500 miles without adjustment.

Supreme Court, sitting in New York which places all cases of alleged ing under the local ordinance, which les for a fine of not more than $10, to have aroused a great deal of in- Some of the anti-automobile papers have been crying loudly for jail sen- and large fines, seem much perturbed the reasonable penalties which are to licted on drivers who forget they have peeds on their cars. It appears prob- that the Board of Aldermen will pass regulations to conform with Justice 's decision. Anticipating this fact, De C. Morrell, the acting chairman of the Committee of the New York Auto- e Club, has written a letter requesting representatives of the club and of the try generally in New York city be given pportunity to appear before the Board. New York A. C. is anxious to see a city ordinance enacted which shall be basis of reckless driving rather than f which a definite rate of driving shall e keynote. It is held that if this is reckless drivers will be the sufferers hands of the police, while drivers who sing due care will not be held to un- nable and foolishly slow speeds.

A. A. Legislative Board Reports

a recent meeting of the A. A. A. Ex- e Committee, Charles Thaddeus Terry a report for the Legislative Board. e Legislative Board has kept in touch the legislative situations in the various s, to whose legislatures statutes relat- o automobiles were presented at their sessions. While the general trend of ation, as gathered from the data col- , seems to be in the direction of rea- leness and a somewhat larger degree irness than heretofore, and to show what of abatement of the unreasoning several States as to indicate an imperative demand for one of two things, to wit: either (1) the speedy enactment of a Federal law covering the field as far as may be; or (2) the enactment thruout the States of a uniform automobile State law framed upon the model of the best of the present State laws, with improvements thereon if possible.

The Board is prosecuting its work along both of these lines and seeking the earnest co-operation of the individual members of the Board to those ends. It will be remembered that the Board prepared and introduced in Congress at its last session a bill providing for the Federal registration of automobiles, and that it is the intention of the Board to press that bill to passage if possible at the coming session of Congress.

The Board asks that a copy of the draft of the uniform State motor vehicle law in its final and approved form be sent to each member of the Board with the request that such member, in case the legislative situation in his State is such as to make it feasible, have the bill introduced into the Legislature of his State, and use his energetic efforts to secure its passage and signature by the Governor of his State.

Morris Park 24-Hour Race

An important announcement has just been made regarding the track racing situation in New York. There has been formed, for exploiting track racing, the Morris Park Motordrome Club, with headquarters in the Times Building. Recognizing the fact that both the public and the trade are much interested in 24-hour races, and because of the failure of the promoting company to secure the Brighton Beach track for another 24-hour race, the Morris Park Motordrome Club has announced a race of this kind to be held on the Morris Park track, together with interesting programs of short races, on September 6 and 7.

Considerations of Motor Car Elements

HUGH DOLNAR.

(The name of the writer of these considerations is well known to our readers as a describer of new cars, and his extended experience as a machine designer and constructor gives value to his deductions and suggestions. Should any of our readers dissent from the conclusions reached in these articles, the columns of the Journal are open to all, in the full belief that free discussion and interchange of opinion is the shortest road to perfection.—Editor.)

High-Class Material in Car Construction

Viewed from the standpoint of "reliability" only, what grade of material should be or must be used in the construction of the best motor car? Is it needful to use chrome-nickle steel and aluminum to the extent now adopted in first-class cars? Should car bodies be made of wood, of steel, of sheet aluminum or of aluminum castings? As to upholstering, the surface of the cushions, curtains, pockets and so on is subject to constant wear from use and cleaning, and there is no question but the best and highest priced material is best, both with regard to elegance and durability, but considerable saving may be made in body trimming by the use of really good and durable material which is what might be termed "best second-class," to finish a body with an appearance of luxury and give a fairly long life at much below first-class total material and labor costs. The sheet steel body is cheapest of all, provided a permanent model can be adopted, since the first cost of material is low, and by intelligent design and expert press and die tool making, the labor cost of such bodies can be materially reduced.

SHEET ALUMINUM BODIES.

Sheet aluminum bodies are much more costly than sheet steel bodies, but can be readily produced by hand in different styles by expert workmen with very few special tools, and thus are often used for special bodies. They are light and fairly strong, and they offer little resistance to blows, being easily dented, but fortunately can easily be put into shape again. This class of body is not as commonly used as formerly.

Cast aluminum bodies are costly, are difficult foundry productions, but are extremely good and durable when of correct design.

WOOD BODIES.

Wooden bodies are made at all prices, and of all degrees of goodness and badness, from the flimsy excuses that begin to show cracks in the salesroom to the highest examples of the coach builders' art, which must be made of selected woods by expert workmen, after being carefully designed. They are very costly and extremely durable.

SHEET STEEL BODIES.

For the cheapest and the moderate priced car bodies, which will soonest appear in final or standard forms permitting the fullest use of machinery in production, sheet steel seems certain to have large employment. For the highest class of work in tonneau and limousine bodies, cast aluminum would be cheapest and best if designs could be repeated, but if the design must be varied to suit individual purchasers, wood is the only available material. A first-class wooden limousine body can be furnisht to the customer for about $2,000.00, the body "in the white," as it leaves the woodworker's hands, costing about $600.00.

Considering the chassis only, can a thoroly good and satisfactory car be made of ordinary steels, with grey-iron instead of aluminum castings, a steel casting or bronze casting front axle in place of a no-weld drop-forging, and a grey-iron crank-box and gear-box, or is it absolutely indispensable that chrome nickle steel and aluminum and high-grade bronze castings should be used at all points?

Chrome nickle steel oil-tempered is very strong, and offers the greatest resistance to wear. It is also very costly in the rough, is very hard to work and is extremely destructive to both dies and cutting tools alike.

Machine steel is a very cheap and abundant material, soft, not very strong, and offering little resistance to distortion by shock. But machine steel is easily worked and can be cheaply stiffened by expert case-hardening and by skillful designing can be used in many places with very good results.

As to aluminum, there is a famine in the land. The one company which is the principal or only supplier of aluminum to the motor-car trade, is now adding a $5,000,000.00 extension to its Niagara Falls plant, which will help, but for 1907 the aluminum supply will govern the production volume of more than one builder of high-grade cars.

Motors on Springs

All car motors are heavy; a 4-cylinder motor weighing anywhere from about 425 lbs. upward, according to the size. If the motor-base lugs reach across and hang on the top edges of the chassis frame sides then sudden movements of the car on rough roads can place severe stresses on the side frames.

To obviate this difficulty and relieve the frame, some makers are introducing springs between the engine and frame.

Where a sub-frame is used for carrying the motor the sub-frame itself is commonly of angle steel, not very heavy, and acts as a very stiff spring in transferring the motor-weight shock to the cross-girts and chassis frame, so that with the sub-frame there is some elasticity in the motor support without introducing springs directly under the motor-base lugs.

The Menges car-motor has 3 long lugs on each side of the aluminum motor base, nearly filling the width between the chassis side-frames. The side-frames themselves have fixt to their inside 3 brackets each,

Hosted by Google

located to suit the motor-base lugs. The two middle base-lugs sit on coiled springs which rest on the middle frame-brackets, while the four end-lugs have coiled springs above as well as below, the lower springs supported, of course, on the side-frame brackets. The bolts which pass t!.ru the frame-brackets and base-lugs have globe-washers under their nuts.

This carries the entire motor on its own springs and so wholly avoids the possibility of any hammer and anvil effect between the mass of the motor, about 600 lbs. weight, and the side-frames.

Altho the vertical movement of the motor on these supporting springs is very small at the ends and hardly more than a mere rocking on the middle lugs, a cushion is a very different thing from a rigid anvil, and almost wholly negatives the destructive effect of a blow, even tho the cushion is but slightly deprest.

Where heavy weights are to be carried on a moving structure of the lightest construction compatible with reasonable expectation of safety, every possible shock alleviation by spring cushioning is of very great value, and the spring-location of most efficiency is between the heavy mass itself and the first of the light supporting members of the chassis frame, as this directly weakens the effect of the blow of the mass unit.

If these assumptions are correct, then the carrying of the motor on local springs permitting limited motion in all directions is sound engineering practice, likely to show to very great advantage in the rough-road work of heavy cars.

The motor supporting springs should have as much flexibility as is compatible with a sufficiently stable motor-support when placed under normal compression, and in well considered forms, as shown in the Menges car it seems that carrying the motor spring supported should make for long life of the chassis frame and the front springs, elements which are among the first to fail when cars are driven rapidly over rough roads.

SPEEDOMETER DRIVING.

Why or how any one ever took up the plan of driving the speedometer from the front wheel hub passes all comprehension. The front wheel is now invariably used for steering, and there is no way to avoid either a universal joint or flexible shaft, if the speedometer drive is taken from a front wheel. The result is a flexible shaft in a flexible brass casing, leading from the speedometer on the front-board to a front-axle bracket with a spur gear and pinion running in the dirt inside the front wheel. All this looks very bright and nice in Madison Square Garden, but is not at all delightful when the flexible shaft goes adrift and winds up on the front wheel hubs with the end tangled up with the axle bracket and nearly puts the car into the ditch.

The writer does not know of one single speedometer flexible shaft that went thru the Glidden Tour in good shape—no matter who the maker was, the speedometer was not in business on any car noticed at Jersey City. Some of the flexible shafts went out of business the very first day, between Cleveland and Toledo, and more the next day, when the cars were all hub-deep in the mud out of Toledo.

The writer saw a design for a speedometer driver, made since the end of the Tour, in which the power was taken from the line shaft and carried forward with plain shafting and gearing, no flexible shaft, to the speedometer on the front board. Some of the French cars drive the speedometer from the line shaft. All chain drives to the rear wheels can have the speedometer driven from the counter-shaft, and all bevel gear drives, where there is but one ratio of gearing to the rear axles, can drive the speedometer from the line-shaft at the rear of the gear-box, without trouble. Where the speed change gear is in the rear axle gear housing, so that there is no fixt ratio between the line-shaft speed and the rear axle speed, the drive for the speedometer could not well be taken from the line shaft.

One thing is sure, however, and that is that no arrangement yet offered in which the speedometer is driven from a front wheel thru a flexible shaft, will stay in place thru hard touring. The last Glidden Tour made that perfectly plain and certain.

There is no real objection to taking the speedometer drive from one of the rear axles, tho there is plenty of opportunity for lucid thought and correct reasoning in designing an ideal speedometer drive, especially as it must contain a speed change that will permit variations of ¼ inches in wheel diameters.

For the plain bevel gear and side chain drive, which are yet almost the only forms used, there is no trouble at all about driving the speedometer from the line-shaft or the counter-shaft, and so enclosing the whole speedometer drive, and making something that can be relied upon.

A speedometer could probably be sold for less than the price now demanded if it was not for the trouble made by the drive, the gear and pinion on the front wheel and the flexible shaft.

The speedometer is a necessity, and it is of great importance that it should be reliably driven, and there is an opportunity to show a lot of good judgment in selecting the initial pont of driving and arranging the wheel diameter changes and compensations, between the initial point and the speedometer on the front-board.

The rear axle is the only initial point that fills all conditions, and perhaps is the best place to begin.

Marvel Automobile Co., Detroit, Mich., has filed a petition in bankruptcy. The three largest creditors are Milton Mfg. Co., $532.86; Long Mfg. Co., $1333.25, and the Class Journal Co., $591.65.

Trade Changes

Auto Goods Company, of Boston, Mass., has removed from room 410, 60 State street, to 95 Milton street.

American Motor Car Company, Indianapolis, Ind., has filed notice of increase in capital stock from $25,000 to $100,000.

Appeal Mfg. and Jobbing Co., Los Angeles, Cal., has removed from 940 South Main street to 631 South Los Angeles street.

Blue Ribbon Horse and Carriage Company, of Bridgeport, Conn., has been succeeded by the Blue Ribbon Auto and Carriage Co.

Coleman, J. C., of Detroit, Mich., manufacturer of steering wheels for automobiles and motorboats, has removed his factory from 234-238 Jefferson avenue to 58-60 First street.

Electric Storage Battery Company, of Philadelphia, has removed its San Francisco sales offices from the temporary location at 11 Hawthorne street to the Crocker Building, that city, where they will be permanently located.

Hercules Auto Specialty Mfg. Co. informs us that the Chicago end of the business, with offices at 115 Dearborn street, has been incorporated for $100,000, full paid, with fololwing officers: J. Arthur Scott, president; G. N. Scott, vice president; D. W. Russell, secretary and treasurer.

Hartford Auto Parts Company, of Hartford, Conn., has increased its capital stock from $1 to $35,000.

Lear, Oscar, Automobile Co., Columbus, O., has increased its capital stock from $200,000 to $250,000, and changed its main place of business to Springfield, O.

Monarch Motor Car Company has removed from Franklin Park and Chicago, Ill., to Chicago Heights, Ill.

Marion Motor Car Co., of Indianapolis, Ind., has increased its capital from $25,000 to [illegible]

Morgan & Wright's Atlanta, Ga., branch has changed its location from 49 South Forsyth street to 92 North Prior street.

Matheson Motor Car Company, of New York, on September 3, will be succeeded by Palmer & Singer Mfg. Co.

Rubber Paint Company, of Chicago, Ill., has been succeeded by Adams & Elting Company, of that city.

Royal Motor Car Company, Cleveland, stockholders on August 3 voted to increase the capital stock from $500,000 to $1,000,000.

Standard Detachable Rim Co., manufacturer of the Ruff detachable rims, has removed its headquarters from 42 Broadway to 1876 Broadway, New York.

Sartus Ball Bearing Company, of New York city, has changed its address from 155 Spring street to 99 Chambers street.

Shoemaker Automobile Company, Freeport, Ill., has increased its capital from $100,000 to $[illegible]

Triumph Motor Car Company, Cragin station, Chicago, Ill., factory, machinery and equipment purchased by Bendix Company, of Chicago.

Turner Brass Works has removed from 65 Michigan avenue, Chicago, Ill., to Sycamore, Ill.

Victor Auto Tire Repair Company, of Passaic, N. J., makers of the Victor inner tubes, has changed its style to Victor Auto Tire and Repair Co.

Ventilated Cushion and Spring Co. has removed its main offices from 2014 Fisher Building, Chicago, to Jackson, Mich.

Fires, Judgements and Failures

Aerocar Company, Detroit, Mich., three creditors filed petitions in bankruptcy, liabilities amount to $250,000.

Bullard Automatic Wrench Co., of Providence, R. I., attached for $25,000.

Davis, Albert A., proprietor of a San Bernardino (Cal.) garage, filed petition in bankruptcy. Liabilities, $6162; assets, $4592.

Duer Auto Company, 24 Richmond street, Providence, R. I., damaged by fire, caused by explosion of gasoline.

Garrett, Timothy, garage, 70 Penfield street, Roslindale, Mass., damaged by fire.

Grout Automobile Company, Orange, Mass., trouble has been temporarily patched up, and the factory will soon be in operation.

Hirsh, F. P., Tower Hill, Ill., garage and repair shop, totally destroyed by fire August 6; insured.

Knox Automobile Company, of Springfield, Mass., outlines plan for reorganization. This plan is to issue preferred stock at 8 per cent. to cover the present liabilities of the concern, amounting to about $560,000, and then turn the company's present capital of $363,000 into common stock; they would thus have $923,000 capital.

Lockwood & Co. (Frank P.), Merrimac, Mass., fire damaged body factory. Loss estimated, $5000.

McTachern, of West Roxbury, Mass., garage damaged by fire, July 20, to the extent of $3000.

Meyercord Company, Inc. (The), of Chicago, decalcomania manufacturers, fire visited their plant, entirely destroying one building. Plans have been completed for the rebuilding on larger scale.

Mack Bros., 532-540 Atlantic avenue, Brooklyn, N. Y., garage totally destroyed by fire. Loss estimated at $110,000.

Pitt, Walter H., and Berthold Lienhardt, individually and as members of the firm of Pitt & Lienhardt, were duly adjudicated bankrupts on June 25.

Pennsylvania Electric Vehicle Company, Philadelphia, Pa., a petition for the appointment of a receiver has been filed.

Safford, W. F., Manufacturing Co., manufacturers of motor boats, Westerly, R. I., have been declared bankrupt.

Shreveport Automobile Company, of Shreveport, La., destroyed by fire July 29.

St. Louis Motor Car Company, of Peoria, Ill., bankrupt, $95,000 of the $120,000 indebtedness of the St. Louis company has been purchased at 25 cents on the dollar on all bills outstanding and payable to the company. If the remainder is acquired the bankruptcy proceedings will be discontinued.

University Garage, on Olive street, New Haven, Conn., damaged by fire.

Western Motor Car Company, Sacramento, Cal., fire of unknown origin entailed a loss of about $1300.

Willis, E. J. Co., 8 Park place and No. 231 West Fifty-fourth street, New York, has made a settlement with creditors at 30 cents on the dollar, payable 15 cents cash and 15 cents in two notes at four and seven months, secured by a deed of trust of the capital stock of the company.

Legislation

MICHIGAN.

Leudington.—Council recently established a speed limit of six miles an hour.

The new law which went into effect June 28 is different from that which preceded it. One of the chief changes is that motorists must pay an annual license fee of $1 instead of $2 for a perpetual license. Also license numbers must be displayed on both front and rear of cars.

The secretary will issue each year a directory of all licensed automobile owners, to be furnished gratis to city or town officials and licensed motorists. The law also provides for the punishment of persons taking a machine without the owner's permission.

INDIANA.

Indianapolis.—City Council has passed an ordinance prohibiting the use of blinding searchlights on motor cars within the city limits, with the exception of the police emergency car, which is allowed to retain its powerful light.

Automobile Club of America Begins To Redeem Bonds

August the first, three months after the opening of the new club house and garage of the Automobile Club of America, $20,000 of the second mortgage bonds were redeemed and cancelled.

Much satisfaction is exprest among the members at this evidence of the club's stability and progressiveness, and the governors are now planning to have at an early date in the fall a meeting of the club members for the purpose of burning the cancelled bonds.

Further blocks of the bonds will be redeemed at short intervals.

The membership of the club is increasing very rapidly and before the close of the year promises to reach the 2000 mark.

Word comes from London that the expected change has been made in the regulations governing the Tourist Trophy contest and the Royal Automobile Club has definitely decided to abandon the contest on the Isle of Man. Instead of this the Tourist Trophy will be contested for in a 1000-mile road test, finishing up with speed and scientific trials on the motor racing track at Brooklands.

Columbia Electric Transmission for Gasoline Cars

HUGH DOLNAR.

NOTE:—The Columbia Gasoline-Electric Car, built by the Electric Vehicle Co., Hartford, Conn., was briefly described page 125, March 1907, and we now present to our readers a detailed description of the electric transmission itself.

The object of this electric transmission is to transfer the power of the motor car gas engine to the car driving-wheels so as to turn them at varying speeds forward or backward, and also to provide an electrical brake which can be used at any speed of the car when moving in either direction and, finally, to supply a coasting resistance, which will prevent the car from running either forward or backward down any incline not too steep to permit wheel-adhesion control of the movements of the car.

SPEED CHANGES.

As is well known, the whole round of mechanical speed-changing devices, including toothed gearing in the sliding gear and the planetary assemblages and friction drives in the form of belts, friction-disks and friction-wheels, has been tried and is now in use in motor cars. The planetary gear changes are effected by friction selection, as are some forms of always-engaged toothed speed-changes. In other forms of toothed-gear speed-changes solid-jaw clutches are used, which cannot be engaged with each other save in certain positions. The friction disk and friction wheel can always be disengaged and engaged, but every change causes some loss of time, during which the motor drive is mechanically interrupted, this being true of all the forms used, thus greatly decreasing the hill-climbing power. It is wholly within the bounds of truthful statement to say that no form of mechanical speed change and control is satisfactory, every arrangement of this kind so far shown having serious faults of its own which cause loss of power, waste of time and constant up-keep costs.

The electric transmission, it is claimed, avoids all these generic faults of both the toothed gear and the friction motor-car speed-changes and control effects because (a), electrical speed-changes can be made instantly, regardless of the relative positions of the mechanical parts (b), because electrical speed-changes in both velocity and direction can be made with no losses due to either friction, inertia, or momentum, and (c), in case of retarding or brake effects, well known to be most destructive to all forms of mechanical brakes when used on long hills, the electric resistance is ideal, since it involves no mechanical contacts and hence does not include the possibility of either excessive heating or abrasion, and so inflicts no injury of any kind on any part of the mechanism of the car.

The two advantages of electric transmission of commanding importance are, the possibility of instant application and the entire avoidance of losses by the friction of gear-teeth or of frictional engagement.

ADVANTAGES OF INSTANT APPLICATION.

It is well known that a good driver can increase his speed by repeated journeys over a given course, because as he learns the road he knows in advance exactly what his car can do on every rise and descent and in every stretch of mud, sand or rough surface, and can have his gear in its most suitable change before arriving at the point where this change must be used to make the car do its best.

On a strange road the driver, even tho very skillful, must always be surprised by unexpected conditions. It is a very common event for a driver to attempt a hill-climb at a too high rate, and then to fail in making the required gear-shift and so take much more than the least possible time of his car in ascending this particular hill.

Again, a car often begins to run down a steep hill in spite of all a driver can do, or in case the brakes do hold the car safely down the hill, they are found to be destroyed by heat and cutting when the descent is completed.

But if a driver can certainly make any speed-change instantly at any time, regardless of relative positions of his speed-changing elements, he is most effectually guarded against surprises of any and every description, since he can suit his car to any kind of road conditions as soon as these conditions are perceived, without causing the drive to let go of the car for a single moment. This possibility of instant speed-change, with no loss of time and no stoppage of driving effect, enables the driver to give his car the nearest approach to a uniform speed that his motor power permits. With all mechanical-control changes there must be stoppage of action, but the electric transmission never lets go of the car.

YIELDING ENGAGEMENT.

The electric transmission is not rigid, altho it is perfectly reliable; it has a fixt and constant slip, which cannot be exceeded, so that there is never any failure to drive, such as is caused by the undesired slip of a mechanical clutch.

This constant slip prevents any engagement shock, and permits the heavy field, fixt to the engine crank-shaft, to be driven at maximum speed at the time of making changes in rate, without injury to the mechanism. In hill climbing the car can be permitted to coast to the foot of the incline while the engine is running free and reaching its highest speed, giving the flywheel field its greatest momentum, and then for ascending the incline, this full maximum engine effect can be at once applied to the car-drive with no shock or injury, the yield-

Hosted by Google

ing engagement avoiding all danger of breakage.

POWER LOSSES BY TOOTHED AND FRICTION GEARS.

These are well known to be enormous in all toothed gear and friction motor-car speed-changes, so that the draw-bar pull of the best motor cars, that is to say the power actually expended by the driving-wheel tires on the road surface to push the car forward, is never more than a small fraction of the horse power developed by the combustion of the fuel in the motor cylinders.

Motor friction may be regarded as the same with all transmissions, since any motor may be used to drive either a toothed gear, a friction gear or an electric transmission gear, hence whatever friction losses can be avoided by installing the electric transmission must be regarded as pure gain, with no draw-back save that of journal friction caused by the added weight due to the electrical installation. This added weight is only a very few hundred pounds at the most, and as it is all carried on ball-bearings and is all in perfect standing and running balance, with no side thrusts whatever, the frictional power losses and consequently the mechanical up-keep charges must be extremely small with the electric transmission.

ELECTRICAL TRANSMISSION METHODS.

Prior to the inventions of Mr. Justus B. Entz in electrical transmission, the only known method of electrically transferring the power of a prime mover, as a water-wheel, a steam-engine or a gas-engine, was to make the motor turn either the field or the armature of an electric generator and apply the electrical current thus generated to the turning of electrical motors which were made to produce the desired useful effect. Where the electrical current generated by the work of the prime mover is to be used directly, as for lighting or for electrical furnace work, this method is very largely used to transmit the power of water wheels to considerable distances, as well as for the local distribution of electrical current to obtain power by driving motors. This same method has also been applied to some extent in motor-cars to avoid the use of storage batteries.

ESSENTIAL ELEMENTS.

To electrically transmit the power of a gas engine to a toothed pinion and so make it turn the driving wheels of a motor car, an electrical "field" can be fitted in place of the ordinary fly-wheel rim and made to surround an "armature" which the field does not touch, but which field, when revolved, will cut the lines of "magnetic force" between the field and the armature and so generate an electrical current. This generation of electrical current takes place at a low speed of the field if the armature is held from turning, or with a small difference in the relative velocities when the armature movement is resisted so that the armature does not turn so rapidly as the field revolves, and the first step taken by Mr. Entz was to apply such a field in place of the engine fly-wheel and make this field surround a generator armature, the shaft of which was connected to the driving pinion of a motor-car rear-axle. This constitutes an electrical transmission in its simplest form and might be made to take the place of the ordinary motor-car clutch to transfer the power of the gas engine to the pinion shaft, but would give a direct, high-gear drive only, with no low-gear or other speed-changes save such as were due to engine speed and no brake effect except to retard the car in coasting backward, leaving the car free to coast forward and with no electrical brake when the car was moving forward, either by gravity, by momentum or by the power of the motor, so that this simplest form of electrical transmission would be of no practical value. Besides the functional deficiencies specified, the excess speed of the field turned by the engine above that of the armature, which is necessary to cause the generator armature to revolve, generates a certain quantity of electrical current which must represent a power loss with this simplest form of electrical transmission, because the transmission as described cannot use the by-product current generated in useful turning effect on the pinion shaft.

Hence the next step was to apply an electric motor armature to the generator armature shaft, between the generator armature in front and the driving pinion in the rear, and this motor armature, provided of course with its necessary coacting stationary field, enabled the current generated by the relative travel differences of the generator field and the generator armature to be used to help in turning the pinion shaft.

This electrical motor applied to the driving-pinion shaft is given two separate windings, which can be placed in series or in parallel, so that the same quantity of current can be made to turn this motor with more velocity and less torque, or with less torque and more velocity, and a small "exciting" battery is supplied to excite the generator field and make it more quickly effective.

Lastly, to obtain a low-speed reverse drive, the pinion shaft was cut in two between the motor armature and the generator armature, and a solid-jaw clutch was placed so as to clutch the two parts of the pinion shaft together and make them turn as one when the forward clutch member was forced to the rear as far as possible, or to wholly separate the parts of the pinion shaft, when the forward clutch member was moved as far forward as possible, and at the same time to so interlock this forward clutch member with the chassis frame as to hold the generator armature from turning. This low-speed reverse is not economical of motor power, but as the reverse is very little used low first cost and convenience are the prime considerations.

This cutting the shaft carrying the pinion

Hosted by Google

and the motor armature and the generator armature in two, and placing the clutch members as specified, so that at the will of the driver the two parts of the shaft can be connected, or can be separated and hold the generator armature still while the motor armature and its shaft carrying the driving pinion are left free to be turned by the action of electric current supplied to the motor fields, gives the electric transmission all the powers required for the perfect handling and control of the car.

THE CONTROLLER.

To surely and quickly produce any of the desired motor-car driving or controlling effects by the use of a gas engine and the electrical transmission, a controller, arranged to be hand-actuated by the driver, is provided. This controller consists of a small horizontal shaft, carried in suitable bearings located on the inclined upper surface of the fuel-tank, under the driver's seat. The controller has fixt to its shaft a 9-tooth retaining ratchet and a spur pinion. This controller pinion is engaged by a hand-moved spur-gear sector of sufficient radius to give the controller pinion one turn with about 120 degrees of movement of the spur-gear sector, the hand lever part of which rises up through the driver's seat at the right hand so the controller sector can be conveniently worked by the driver's right hand.

Besides this controller there is one mechanical brake pedal which operates when pushed forward, first to electrically disconnect the engine from the driving-shaft and then apply the external, rear-hub-drum, mechanical brakes. Besides this mechanical, exterior brake effect applied by the right pedal, a left pedal when pushed forward, applies the rear-hub-drum, internal, expanding brake-shoes only, producing no other effect.

dition to all of these brake effects, the rearward "sprag" effect is always automatically operative.

The two reverse speeds are obtained by un-clutching the two sections of the pinion and armature shaft, and locking the generator armature so that the whole power of the gas engine is applied to the generation of electric current to supply the electric motor which drives the pinion shaft in the reverse movements.

WEIGHT REDUCTION AND POWER SAVING EFFECTED.

Altho this form of transmission was briefly described in the March, 1907, issue of the Journal, page 125, as many do not yet fully understand its operation, the following detailed explanation with diagrams is given.

The diagrams here reproduced are not intended to represent actual constructions, but the principles only.

The numerals given in connection with these diagrams are chosen for convenience and plainness of illustration and ready comparison, and the same basic values are used in the three diagrams; while the numerals are not exactly those of practice the conclusions exhibited are indisputable.

What was known before the invention of Entz is shown in Figure 1, and represents the principle only as now used for the reverse. The diagram shows the flywheel generator-field as fixt to the engine crank-shaft and surrounding the generator armature, A, which is prevented from turning by the resistance arm. When the engine turns the crank-shaft the whole power is expended in the generation of electrical current, which is conveyed by the conductors to the motor, this motor shaft having fixt to its right end a bevel pinion engaging a bevel gear, the turning of this pinion

Fig. 1. Generator and motor each 80 per cent. efficiency. Engine 500 R.P.M., 100 torque. Mortor 500 R.P.M., 64 torque. Efficiency 64 per cent.

There is also a third extremely powerful brake effect, produced by placing the controller handle in the braking position, reversing the currents in the electric motor field, so that this motor becomes a dynamo, and gives a sufficiently powerful retardation to bring the car at once to a very low speed. A modification of this effect permits any degree of electrical forward brake effect to be applied to the pinion shaft, so as to regulate the coasting speed of the car to any desired rate without the use of the mechanical brakes, thus controlling the movement of the car while coasting down long hills, forward, without mechanical friction and without injurious electrical action. In ad-

and gear being the load to be overcome by the motor.

The weights required to transmit a certain gas engine power by the mechanical and electrical linkage shown in Figure 1, and the losses and efficiencies resulting from this form of electrical transmission are all well known.

The values chosen are arbitrary selections, but are approximations to results obtained in practice. Assuming the engine to make 500 revolutions with 100 constant torque and the motor and generator to each show 80 per cent. efficiency, 10 per cent. of loss by friction and 10 per cent. loss by electrical resistance, the motor will show

Hosted by Google

64 torque with 500 revolutions, which is equivalent to 64 per cent. efficiency and 36 per cent. transmission loss.

As in the case of all far-reaching improvements, the basic modification made by Mr. Entz to reduce the machinery weights and power losses of electrical transmission is extremely simple, so very simple that it can be clearly shown in a single diagram, as Figure 2.

Fig. 2. Reduced speed. Engine 1000 R.P.M., 100 torque. Motor 500 R.P.M., 164 torque, efficiency 82 per cent. Exactly the same electric output from generator to motor, same speed differences, but 2½ times the output for the same weight and same machine as in Fig. 1.

Fig. 2 has precisely the same parts as Fig. 1, but the form of generator armature resistance is changed from that of an arm to resist the generator-armature rotation, to the prolongation of the generator shaft and the mounting of the motor-armature on this shaft-prolongation, with the bevel pinion, representing the work, at the right, as before. The conductors from the generator-armature to the motor armature are retained and the new effects gained are two (a), the driving of the bevel pinion principally by the torque of the generator armature on its shaft and (b), the driving of the electrical motor by the current generated by the excess of the generator-field revolutions over the generator-armature revolutions.

power that is efficient in overcoming the work resistance, whereas in Fig. 2 the electric motor is called upon to transform only a small part of the energy developed by the gas engine from electrical current to mechanical movement.

Not only is the mechanism made much lighter and cheaper by the changes shown in Fig. 2, but the efficiency is enormously increased, so that assuming 1000 engine revolutions with 100 torque and giving the electric motor and the bevel pinion 500 revolutions as before, the total torque of the armature and pinion shaft must be 164, composed of the 100 torque assumed and the 64 torque due to the driving effect of the electric motor which is driven by exactly the same electrical output as in Fig. 1, where the generator field had 500 revolutions more than its stationary armature, same speed difference as in Fig. 2. This places the efficiency at 82 per cent. for Fig. 2 as against 64 per cent. for Fig. 1, while Fig. 2 can transmit 164 torque as against only 64 torque in Fig. 1.

Various effects, subsequently specified, are produced by different applications of electric current to the electric motor, placed

Fig. 3. The clutch generator short circuited on itself. High speed direct drive. Engine 1000 R.P.M., 100 torque, shaft 950 R.P.M., 100 torque, efficiency 95 per cent. No current thru motor. No external electrical work. Output three times that of Fig. 1.

This gives the bevel pinion representing the load the full combined torque of the engine and the electric motor, which is over 2½ times the power transmitted in Fig. 1, and this increased effect is gained without any loss to offset the gain in power transmitted, but the engine must be run at twice the former speed, thus generating more power, so as to give the crank-shaft 500 turns more than the generator armature, the same as it has in Fig. 1, where the armature is held stationary.

Thus in Fig. 2 by far the larger part of the power is transmitted mechanically thru the armature shaft itself, while the electric motor has only a small part of the total work to do, and can therefore be very much smaller, lighter and less costly than if it had all the work to do as it has in Fig. 1, where the electric motor transmits all the

as shown in Fig. 2.

Fig. 3 is the same as Fig. 2, save that the generator armature is not wired to the motor armature, but is short circuited upon itself. Supposing the engine to make 1000 revolutions, 100 torque, then the generator armature will make 950 revolutions, because of the 10 per cent. electrical resistance of the generator. This gives 95 per cent. efficiency, since there is no torque loss, consequently the bevel pinion will be given 950 revolutions, 100 torque, with no current thru the motor, no external electrical work, and with a power transmission capacity 3 times as great as that of Fig. 1.

Hence it appears that if Fig. 1, representing the state of the art prior to Entz, has an efficiency of 64 per cent., Fig. 2, representing the Entz first modification, has 82 per cent. efficiency while the second modifi-

Hosted by Google

rect drive with 95 per cent. efficiency.

In the diagrams one motor only is shown, but in practice it would be necessary to use more than one motor in the system shown in Fig. 1 in order to obtain the necessary number of speed changes. In the Entz system the motor armature has two windings. Five forward speeds are obtained in all of which the full engine torque is transmitted directly to the driving shaft, the same as shown in figures 2 and 3 which exhibit two of the five forward speed variations, other variations being obtained by placing the motor armature windings in series or parallel, and by shunting the fields of the generator and motor. As the controller passes to each higher speed position the torque which the motor adds to the driving shaft is reduced, and also the counter electro-motive force or electrical back pressure developed in the motor is reduced, thus requiring less speed difference, or slip, between the generator field and armature to overcome it, until in the fifth position there is no counter electric motive force to be overcome, and the only speed difference between the generator field and armature is that required to overcome the electric resistance of the generator circuit. This slip or loss of speed only reduces the maximum speed of the driving

If it is wished to slow up while cending a hill to take a bad wate it is only necessary to slacken the spe the engine by a partial closing of the t tle. This slows down the field to a below that of the engine, all generati current and clutching action ceases an car drifts, or coasts, over the obstru Upon opening the throttle the engine s up without any load being imposed up until it reaches a speed greater than of the driving shaft, at which point ge tion of current and the clutching actio gins, but with a quick opening of the t tle the engine may speed up to one o hundred revolutions faster than the dr shaft before it is fully loaded, thus gi augmenting the momentum of the gene field which is equal to that of a 350-lb wheel, which, when applied by elastic cl ing effect, pulls the car up to full again at a surprisingly rapid rate, more rapidly than is possible in a car any form of mechanical transmission.

The fact that all clutching action c when the driving shaft is turning faster the engine, produces the same effect as of a coaster brake on a bicycle, and on grades the engine is allowed to run s under control of its governor while th coasts with absolute freedom and sile

Columbia Electric Vehicle Company's 1908, 7-passenger Electric Transmission Touring car, c trol side. Note absence of brake and gear shift levers.

The specifications are: Wheel-base 124 ins., gage 55 ins., Electric Transmission, 5 forw speeds and two reverse speeds. Electric brakes for all speeds forward and backward, also elec down-hill hold-back in both directions, which does not slide the wheels, but holds the car t speed of one or two miles per hour. Powerful exterior and interior rear-hub brakes are provi pedal actuated, for use if the electrical control should be absent.

The motor is 4, vertical, 4-cycle, water-cooled 5½x5½-inch cylinders. The body is a side trance tonneau, doors swinging to rear, for 7 passengers, two on revolving chairs in front of tonneau seat. The tonneau is extremely wide, giving ample room. Weight about 3900 lbs., ta filled. Price $6500, including 5 lamps, batteries, horn, ammeter, mats and tools. Cape top ex

possibility of injury to the apparatus.

CONTROL.

he spark and throttle levers are on top he steering wheel. The left large pedal ies the external, ordinary, rear-hub-n brakes, and the right large pedal ap-s the internal expanding shoes to the e drum. These are mechanical brakes ordinary action. The small horizontal al is the accelerator and opens the throt-when deprest. The throttle is normally er governor control. A small, vertical-uided, hand-worked slide which stands ow position when the clutch is engaged, in high position when the clutch is dis-aged and the generator armature is held ionary, all as in the diagram Fig. 1, is ted outside the car body, at the driver's

ntrol levers and pedals of 1908 Columbia tric Transmission Touring Car. Description in

t hand. All electrical changes are made placing the controller handle in 9 differ-positions, retained by a 9-tooth ratchet, to the controller shaft, which is engaged a spring-actuated roller-pawl. The con-ler handle in the extreme forward posi-gives high speed, diagram Fig. 3. Next tion to rear gives a reduced forward ed, with the motor armature windings in llel, and a weakened motor field. Sec-position to rear gives third speed, mo-windings still in parallel. The third tion gives third, yet lower forward rate, ling in parallel, motor armature wind-in series. The fourth position gives speed forward, winding in series, gen-or field weakened by a shunt. The sixth roller handle position is the neutral, no

tion to accompany the driver of a Columb car fitted with the Entz form of Electr Transmission in the 1907 Glidden Tour wa accepted, the writer joining the car a Cleveland and continuing from Clevelan to Toledo, South Bend, Chicago, Sout Bend, Indianapolis, Columbus, Canto Pittsburgh and to within about 25 miles Bedford Springs, where long hills entaile low-speed work and failure to open ventila ing doors caused some of the soft-solderin of the motor armature retaining bands give way, causing a short circuit, which pu the car out of the tour. The distance co ered was something over a thousand mile and was made with absolutely no mishap delay at all due to the electric transmissio

On the run of July 10, Cleveland to To ledo, 121 miles, there was only one plac rule in force, disqualifying any car passin the leader, or chairman's car, except in cas the leader was disabled. The running rul forbade racing and obliged a leading ca to give room for passing when requeste Under these rules the cars which had spee and hill-climbing power took precedence they pleased, and as the dust was very ba indeed the cars which could do so we ahead and picked individual positions fo themselves, clear of the dust clouds.

It very soon became evident that the Co lumbia Electric could take any position th was desired, and that, greatly to the ob server's astonishment, it could pass an thing overtaken when climbing a hill.

The lighter cars which could keep out our way on the level were passed easi when going up hill, and it came to be ou regular practice when we wanted to pass make the attempt on an incline, the steepe the better for us. The driver's method wa to run the car down hill coasting, with th governor holding the throttle at low fu supply and the generator over running i field, so the coast was made with almost resistance; when the car began to climb th next hill the accelerator pedal was depres thus giving the motor high speed, and soon as the generator field, which takes th place of the engine fly-wheel, overran i armature the car would invariably accelerat no matter how steep the rise was. It wa only on long hills and over bad roads th low gear was used, and the Cleveland-To ledo run was made on high gear almost quite exclusively, the road performance b ing ideal.

Toledo to South Bend course, 166 miles, was covered after a heavy ra in the night and this day's work include miles together of deep mud, where all th

hich should not have taken more than a uarter of an hour at most, but which, thru arious mishaps, including the dropping of bolt down past the cam-shaft into the ank-box, forcing the pulling down of the l-basin, and then a long delay in timing e commutator, occupied about five hours. Then we were finally right we flew over the miles to Chicago at a fast clip, but were eavily penalized for our delay, which had othing whatever to do with the electric ansmission.

Pittsburgh to Bedford Springs, 97.2 miles, as over long hills with stony roads and ater breakers. The car was stopt on a ood stretch of road and refused to start gain.

A roadside inspection led to the belief at the insulation between the collector ng had failed, and the car was withdrawn om the Tour. It was afterward discov-ed, at the factory, that nothing having any ectrical function was injured in the slight-t degree; all commutators and brushes ere in absolutely perfect condition and all indings were in place. What did happen as this: The motor armature windings are around the turns of wire and soft sold One end of one of these bands lifted allowed one end of the binding wire coi escape and this, unwound, was long eno to reach over to the armature commut and establish a short circuit. If the sol ing had been thoro at first, this acci would not have happened, or if the vent ing doors of the motor casing had b opened it is not likely that the band would have opened. The accident wa the most trivial nature, but it resulte the withdrawal of a car which was ot wise in perfectly good condition, and i impression among the Tourists that withdrawal was due to some electrical hap, when the whole electrical part of transmission was in perfect condition, commutators smooth, and none of graphite brushes even worn down t bearing.

The time of our finish stop was the showing of any electrical difficulty, and curred when the car was within 25 mile Bedford Springs and had covered ove thousand miles of the Glidden Tour in most successful manner so far as the e trical transmission was concerned.

The new 35 H. P. "Mile-a-minute" Autocar roadster, made by the Autocar Co., Ardm Pa. It is something decidedly new, not in mecha nical features alone, but in the finished eff which is a pronounced color of cirulean blue an d crimson. This striking combination of c is most attractive, and in strong contrast to the usual quiet effects as seen in the Autocar D tor's car.

The 1908 MITCHELL

at all agencies

September 1, 1907

The 1908 Mitchell, the finest touring car in the world for $2000 as well as the runabout and the NEW Mitchell Roadster shown at all agencies September 1, 1907. See them. Say to any Mitchell agent—"Show Me." He'll show you in a Mitchell for 5 miles or 50 whichever you say. Convince yourself that for power, control, silence, speed and sweet running there is nothing can equal the 1908 Mitchell at the price.

The 1907 Mitchell a Winner

At Hamline Track, St. Paul, Ed Zerbies in the 24 hour race, after wrecking two cars on the fence at the turns because of the dust—having no other car, borrowed a 20 h.p. Mitchell Runabout from a doctor in the crowd and drove it for nearly four hundred miles until another Mitchell 35 h. p. could be secured. In the face of this awful handicap Zerbies finished only 28 miles behind the winner who drove a 40 h. p. car, selling for over twice as much as the Mitchell, and in addition broke all previous world's records for 24 hours—183 miles.

The 1908 Mitchell chassis is a refinement of the 1907 with all the latter's good points and the same standard construction. You can't afford to overlook the 1908 Mitchell.

BRAKES.

The braking system consists of two external and two internal camel's hair faced brakes on the rear wheels; one set being operated by a foot pedal, the other by the hand lever. An equalizing rod is used on both brakes which causes them to be applied on each wheel with the same tension. These levers are held in place by long springs connected to the rear cross member of the frame.

FINISH.

The standard color is black with gold striping, back corners paneled in deep, rich maroon, while the molding effect on the body is done in dark brewster green, making a beautiful combination. The upholstering is all in black, done in either dull or bright finish of the best quality of goat's skin, in either pebble grain or French finish.

Motoring is Healthful

The hospital records of London contain interesting observations recently made on the influence of motoring on the general nutrition of both healthy and anaemic subjects.

The individuals experimented on were taken daily on a motor run of from 100 to 200 kilometres at an average pace of 40 kilometres an hour for eight or ten days. During this period it was found that the number of red corpuscles increased in large proportion, as well as their hæmoglobin content.

A further beneficial effect was the influence on sleep. With normal subjects sleep was more prolonged, and in the case of neurasthenics, who were suffering from insomnia, the power of sleep was completely restored.—New York Sun.

Personal experience has shown the writer all the above specified advantages as resulting from motor car riding. Very often a ride of 20 or 30 miles at the end of a busy day has brought refreshing rest and a sense of increased vigor, but this only in case of an open car or a car with a cape top and open all round. The writer has believed and yet believes, that the surprisingly speedy rest and recuperation derived from motor car travel is due to the agreeable movement and the rush thru fresh air.

The American Consul at Breslau, Germany, states that there ought to be an opening for American motor boats in Breslau, if properly introduced, as there is a large class

Elmore Valveless 2-Cycle

For all practical purposes the grandest performance of this or any previous Glidden Tour."

hat was and is the consensus of opinion concerning the wonderful achievement of the valveless two-cycle Elmore in coming through the Glidden Tour with bonnet locked and sealed.

t the outset good friends of the Elmore shook their heads doubtfully and said: "You're running a risk."

/e knew we were not.

very Elmore owner knew we were not.

/e've been preaching and proving for years that all the Elmore engine needs is a good fat spark—that the continuous impulse principle eliminates every weakness that would make such a test a dangerous risk for the four cylinder type.

/e knew that unless it was wrecked by accident it would not be necessary for a human hand to touch the Elmore engine.

/e proved that in the last Glidden Tour—but we wanted to make the proof so conclusive that the whole world would know it.

So, in the presence of a committee in Cleveland we locked and sealed the bonnet and relinquished the key. If we won—it meant that the most brilliant performance of any and every other car was outdone and outshone.

They could coax and tinker, renew, repair and replace—we had voluntarily put the Elmore engine to the most terrific test to which any car in this country has ever been subjected.

We won—just as we have won time and time again in the hands of hundreds of owners who have put the valveless two-cycle engine into direct contest with the best four-cycle cars made.

Just as quickly as it can be done we're going to put the story of this wonderlul tour into print.

In the meanwhile, you will want to know all about "the car that has no valves"—the car that is making automobile history—the car that cannot keep up with the demand while many four-cycle cars are languishing.

METHODS OF DETERMINING HORSE POWER.

Pomona, Cal.

The relative power of engines is in proportion to their piston displacement, is it not? Instead of the elastic and wholly unreliable "horse power" measurement, would it be a fair rating to adopt an arbitrary unit of power, say 10 cu. ins., and let the piston displacement divided by this unit represent the power of an engine. For example: Cadillac, 1 cyl., 5x5 inches piston displacement 98.15 cu. ins. divided by 10 equals 9.8 units of power (catalog power 10). Thomas "Flyer," 4-cyl., 5½x5½-in., piston displacement 522.67 cu. ins., divided by 10 equals 52¼ units of power (catalogue 60 H. P.). Fiat, 6 cyl. 5x6 1-32 inches, piston displacement 710.35 cu. ins. divided by 10 equals 71 power units (catalogue 50 H. P.). By the A. L. A. M. formula D squared multiplied by N divided by 2.5 equals H. P.

1-cyl. Cadillac, 10 H. P. (catalog 10), piston displacement rating 9.8.

4-cyl. "Flyer," 48 H. P. (catalog 60), piston displacement rating 52¼.

6-cyl. "Fiat," 60 H. P. (catalog 50), piston displacement rating 71.

4-cyl. Northern, 40 H. P. (catalog 50), piston displacement rating 37.3.—WHEELER.

The power of an engine should be properly exprest by its piston displacement in any given unit of time. Since, however, piston friction is the limiting factor in the matter of engine speed, it is customary to assume that an engine is capable of 1000 ft. per min. piston speed. In my formulas I have assumed 750 ft. per minute as the maximum piston speed and it makes no difference whether the stroke is short or long, for the area of the piston multiplied by the piston speed will give the displacement per minute; so my horse power formula is D squared divided by 3 equals H. P.

The formula recently adopted by the Automobile Club of Great Britain and Ireland and the A. L. A. M. is based on 1000 feet piston speed per minute, and is N multiplied by D squared divided by 2.5 equals H. P. From this you will see that the principal difference is in the assumed maximum practical piston speed.

The method you suggest is a good one and has been used. The A. C. of France used a constant of 12 cu. ins. per horse power. This was several years ago when horse powers were not rated so high as at present, probably because they figured on a lower piston speed. The objection to your method is the laziness of the average man's mind. He can easily square the diameter but to figure the length of stroke and the number of strokes per minute, so as to get at the piston displacement per minute is a task of such increased difficulty that he will not take the trouble. It is therefor better to assume a maximum piston speed which permits neglecting the length of the stroke, and with a proper constant the area of the piston need not be figured, for the areas of circle are proportionate to the squares of their diameters. This therefor makes a result substantially as accurate with much less mental effort. Your error lies in assuming that a piston displacement per stroke is the determining factor, but if you reflect you will see that it is the displacement per minute or unit of time that counts. You will also recognise that a short stroke motor can make more revolutions per minute without exceeding a given piston speed than can a long stroke motor. In regard to the discrepancies noted by figuring and the makers ratings, no notice of this need be taken, as most manufacturers' ratings are purely arbitrary and bear very little relation to the averge actual horse power developed by their engines.—C. E. D.

HOW MUCH DOES A GAS ENGINE CHARGE EXPAND AFTER IGNITION?

Where can I get data as to how much a charge of gasoline vapor, mixt properly with air, will expand after igniting, at pressures ranging from atmospheric to, say, 100 lbs.? I suppose someone has determined this by experiments?

I do not know where such a table can be found. By examining an indicator card you will see that the maximum expansion pressure is about four times the compression pressure, and this is probably near enough for practical purposes. Gases vary in volume in proportion as their pressure or temperature varies from the absolute, so that compressing a perfect gas at constant temperature to twice its pressure will cause it to occupy half of the original volume; and heating a given volume to twice its original temperature, measured from the absolute zero, will double its pressure. The charge in a gas engine is not a perfect gas, but the variation from the theory is so small as to be neglible. Pressures for these purposes are figured from 14.7 lbs. below atmospheric (gage) pressure; and temperatures are figured from the absolute zero, which is 273 degrees centigrade or 491.2 degrees Fahrenheit below the freezing point of water. Roughly, you can compute the absolute zero as 500 degrees below atmospheric temperature. While the combustion temperature is probably 2000 degrees above, which corresponds with the indicator card. As a matter of fact the explosion temperature is probably higher than this, but there is some unexplainable heat lost, which prevents a theoretical expansion and pressure being reached.—C. E. D.

A NEW CARBURETOR ARRANGEMENT.

Hampton, Iowa.

I noticed in one of your recent issues an article relative to the difference in the power of a car in morning and evening of a hot day. I also have marked this and have been trying to develop this condition during the heat of the day. My experiments have developed a carburetor made with a series of pipes in the gas tank so arranged as to create a constant action of the gasoline, which causes a spray and the lowering of the temperture of the mixture, thus giving greater expansion to the mixture. The air is drawn thru the gasoline in the tank by suction of the engine. The mixture caused by this action is too rich, so I have constructed a sliding valve near the engine, whereby I throttle the air. I also have a flutter valve near the engine. so in case the intake valves fail pressure is prevented from entering the tank at my sliding valve, provides a release. Have tried this device on a two and four-cylinder engine. While I drive a single cylinder car. In each case I find a marked difference in the increase in power, and find I can control the mixture at will to any consistency desired with the throttle, and I can take all the advantages desired in country driving to save gasoline and cool my engine. Because, in coasting a hill, I open the throttle, which admits pure air into the cylinder and stops the flow of gas entirely. I have also placed a governor on the pipe leading to the engine, whereby air is automatically taken into the mixture. This valve is in operation only when starting the engine, so as to have it run at a given speed until the operator manipulates the throttle. Thus I have done away with all adjustments, for everything is fastened stationary. There is absolutely no chance of being bothered with dirt or water in any reasonable quantity, as the smallest pipe employed is three-quarters of an inch in diameter. My car never fails to start with the first charge of gas, and weather conditions seem to make no change, as I have operated in severe cold. I have a connection to the intake to provide warm air for winter use. I find that the greater the demand by the engine the better the mixture, as the spray is finer and inexhaustible in its supply. I never have been able to get this to miss fire as others I have had seemed to do. When running fast, if I shut them off and then started up suddenly, they would fail to take hold for several explosions for some cause unknown to me. It looks good to me, but as I am merely a novice along these lines, would like very much to have you comment and advise as to whether to push same or not.—G. M. RODNER.

Your description of the carburetor sounds well. The perfect carburetor has not yet been put on the market. The surface or bubbling carburetor gave a gas as your device seems to do. It was very economical but delicate. It required constant adjustment for various speeds, and was not so satisfactory as the spray device now generally used. Possibly your device combines the advantages of them both. Show it to several of your friends and let them sign a written description of it, so that you will have proof of what you have invented. This will protect you and permit you to show it to others without much danger of having it stolen from you. Then get in touch with people having carburetor troubles and supply your device. They will gladly pay a good price for a good article. It is my opinion that the carburetor is the most neglected part of the auto to-day. When you have made and put into use several of your devices, you will then know whether they are good enough to warrant patenting and manufacturing for the market. It is useless to spend money on patents until you know that the article is right and the market waiting for it.—C. E. D.

GASOLINE IN THE CRANK CASE.

San Francisco, Cal., June 21, 1907.
419 Foerster street.

I have a 4-cycle, 4-cylinder gas engine which acts very peculiarly; three cylinders consume the fuel perfectly, while cylinder No. 3, which is second in time of firing, explodes, yet the fuel goes thru in liquid form. The ignition is make and break. The fuel goes thru the cylinder into the crank case, so that in 15 miles' running it cuts the oil in the pit so that it is perfectly useless.

All valves are mechanically worked and are all set alike. Inlet valves open and close on centers, exhaust valves lead by about 15 seconds and close on centers. Inclosed I send you a correct sketch of the inlet pipes.—W. F. P. SCHNEIDER.

It seems incredible that you should have the trouble you mentioned. First, your carburetor should deliver a gas, not liquid. Ordinarily this is in the form of a spray which may get past the inlet valve in small quantity. It can hardly get farther for contact with the hot walls of the cylinders will vaporize such fine particles and prevents their remaining on the walls. It would seem that the gasoline must get into the pit in some other manner. If the rear cylinder was giving the trouble, I would assume that your engine was considerably inclined and that unvaporized fuel would carry to the lower end of the pipe, but since this is not the cylinder giving trouble, it is quite evident that this explanation will not serve. The carburetor is located near the faulty cylinder, and I think it likely that gasoline may be blown thru a leak in the carburetor and against the outside of the engine, and thus reach the interior, cutting the oil as you say. Look at the joint between the ports of the crank case just below the carburetor, and also see if the carburetor floods or drips much. Careful search should locate the trouble and we will be pleased to hear what it was when you have found it.—C. E. D.

MUFFLER INCREASED SOUND OF EXHAUST.

Brooklyn, N. Y., June 26, 1907.

Will you kindly tell me thru the columns of your magazine why my 45 H. P. car, with a muffler on, makes a noise as tho the cutout was half open, and without a muffler makes no noise at all, no matter at what speed the motor is running? Has the setting of the valves anything to do with it or not?—H. E. P.

The condition you recite is an unusual one, but it illustrates beautifully my contention that the muffler effect is a matter that can only be found by trial. If the pipe and passages are such as to break up the sound vibrations pretty fully, it is possible that the muffler may increase the sound just as the bell of a horn does the sound of a reed. I do not see that it is possible to make the matter clearer to you. It is well known that a fiddle would make little noise without its sounding board. The object of the muffler is to break up the puff of the motor, and in your case it evidently does the other thing. Try changing the length or shape of the muffler or the pipes to it. I have found that a few dents knocked into the muffler with a hammer will sometimes improve its muffling quality. Irregularity is a valuable feature in a muffler, for it causes interference of the sound vibrations.—C. E. D.

Hazleton, Pa., July 9, 1907.

I have a 4x4, air-cooled, 4-cycle, single cylinder runabout. Am remodeling same. Would it be advisable to bore a ½-in. hole in cylinders wall just over top of piston, when down, for an auxiliary exhaust, strapping a pipe connection outside, to the muffler? One mechanic here seems to think that it will interfere with the perfect lubrication of the cylinder over the hole. If this is so, how do 2-cycle engines manage? Such a hole ought to be small enough to cause little inconvenience of that sort, yet furnish some relief to the regular exhaust valve and back pressure in the cylinder. According to current Horseless Age (July 3), it is a good thing.—EDW. E. HOWE.

The auxiliary exhaust can be made as you suggest. Several small holes are probably better than one large one. The piston rings will spread the oil so you will not have much trouble. Unquestionably the auxiliary does save the exhaust valve from a large amount of heat. I doubt if the running of the motor will be improved unless the present exhaust valve is too small, but it may prevent overheating if the motor has a tendency that way.--C. E. D

RATIO OF ENGINE TO REAR WHEEL SPEED.

July 25, 1907.

Kindly advise me thru the next issue of the "Cycle and Automobile Trade Journal" what size side sprockets are right to use in a car weighing 2300 lbs. and an engine 4½ by 5 in., the rear sprockets have 36 teeth in them? The bevel gears in the transmission are of equal size, therefore on the high speed the jack shaft goes as fast as the engine. Also what should be the ratio of the speed of an engine of that size, to the speed of the 34-in. rear wheels?

C. H. LEPHARDT.

The gear ratio should depend on your roads. You do not say how many cylinders you have. Ordinarily the engine on high gear should make 3 or 3½ turns to one of the rear wheels. If in a bad roads country or small engine more than this. This would require front sprockets to have 10 to 12 teeth. C. E. D.

KNOCKING UNDER FULL LOAD.

Grand Forks, N. D., July 15, 1907.

In the June issue of the "Cycle and Automobile Trade Journal," under the title "Overheating of Air-cooled Motors," you state "they are a little more likely to knock at full load." I would like to know your theory as to cause of this? That is: Why should an air-cooled motor be more likely to knock than a water-cooled motor? An answer thru the columns of the "Cycle and Auto Trade Journal" will be appreciated. J. L. ROBERTSON.

Knocking or pounding is very generally a symptom of overheat or lack of oil. The water-cooled motor is practically always too cool in order that it may safely be kept from overheating. It, therefore, seldom smokes its oil away and knocks because its cylinder walls are dry so long as oil is feeding properly and usually it is given less oil than an air-cooled because of this fact. Being cool it is not so likely to carbonize the oil as is a hotter engine, altho this is rather a matter of excess of oil and fuel than of heat, for if there is no excess the heat cannot carbonize. Particles of carbon do no harm until they get hot, which they do quicker in a hot engine. So the air-cooler is a little more likely to give trouble from these causes. But there are air-coolers which keep even cooler than a watered engine, and so it is a matter of design. Sufficient surface and air will keep the engine cool in either case. The water is most regular and most troublesome. The air is most economical and simple. Take your choice. C. E. D.

COULD NOT KEEP FLYWHEEL TIGHT.

Louisville, Ohio.

Through "The Cycle and Auto Trade Journal," would like to ask your advice. I have an automobile engine, single cylinder, bore 5 ins., stroke 6 ins., compression space 30 cu. ins.

My first flywheel would work loose and I kept setting up the key until the hub split. I put on a new flywheel with the same result. I then shrunk on a heavy steel band over the hub and drove the key in as tight as I could get it. This held for some time, but at last the hub twisted off from the wheel.

It was very hard to turn the engine over against the compression, and when running slow it was very jerky. I have concluded that I have too much compression and would ask you how many cubic inches compression space a motor of this size should have.—CHAS. K. HOOD.

If your motor does not ignite prematurely I would not assume that the compression space is too small. A high compression motor is capable of high speed and the makers probably knew what they were about. Your piston displacement is about 120 cu. ins., so the compression space is 1-5 of the total cylinder contents. This is smaller than I like, ¼ is quite common and 1-3 often used with success. It may not be convenient for you to shorten the connecting rod or lengthen the cylinders by a ring under the head. I would therefor prefer to attack the flywheel hub problem. Either the hub was too small in the first place or the key did not fit properly. Keep in mind that the key should be tight sideways. Many people imagine that the key should be tight top and bottom, and this is what splits many hubs. It also throws the flywheel out of true. Because of the difficulty of holding a flywheel to a gas engine shaft of the usual size, it is common and the best practice to form a flange solid with a shaft, to which flange the flywheel is bolted.—C. E. D.

2 Cycle Engines

HUGH DOLNAR

Last winter I intended to build a 2-cycle engine with a disc crank case inlet and piston and inlet to cylinder, the same as the Dorville Libby described in the July "Cycle and Auto Trade Journal," tho I had never seen one or heard of an arrangement similar to the piston of the Dorville Libby engine. I did not build, because I was afraid that the incoming charge would not keep this style of piston cool as an air-cooled engine which was what I proposed to build, tho since I have thought it would. Do you think a machine with piston of this style can be run successfully air-cooled? Is this style of piston patented? Cannot one make any patented article for their own use? WM. T. SMITH.

The Dorvill Libby, "Atlas" engine would probably air-cool as well as any other 2-cycle engine using crank-box pressure cylinder supply. The piston head is better cooled than with the deflector on top of the piston. The 2-cycle motor water-cools more easily than the 4-cycle, so that the radiator which perfectly cooled two, 2-cycle, 3½x3½-in. cylinders had to be considerably enlarged before it would cool four, 4-cycle cylinders, 3½x3½ ins. in the same car, both engines doing the same work and driving the car the same speed on the same roads. The writer believes that the 2-cycle motor with an open crank-box and separate supply cylinder, can be well and easily air-cooled.

The Frayer-Miller Company is having much success with air-cooled commercial cars, and new air-cooled car-motors just now completed, and which will soon be described in the "Journal." The writer is very confident that the final car-motor will be 2-cycle, air-cooled, with a charging-cylinder supply.

The piston and port construction shown in the Dorville Libby motor is said to be a German invention, patented some years since, date not now at hand. See Heerman's 2-cycle motor, Journal, July, page 166, for similar piston.

No; you cannot make a patented article without infringing the rights of the patentee, tho you would not be likely to be molested for an experimental construction. H. D.

Chicago, July 15, 1907.

1. In a 2-cycle engine is there any objection either in theory or practice to the use of a compression cylinder, except added weight and cost?

2 Is there any objection to introducing the charge into the power cylinder at from 30 to 75 lbs. pressure, gradually decling to zero or atmosphere at the close of the port?

3. Will the heat produced by the compression cause the charge to enter the power cylinder in an expanded or attenuated form or will the rapid expansion from the compression reduce the gas to its former or nearly former volume?

4. If the connection between the compression and power cylinders is not unduly long or large and a check valve is located in it near the compression cylinder is there any necessity for having the compression cylinder any larger than the power cylinder? That is, will not the first stroke or two fill the connection, and since it is trapped between the power cylinder and the check valve

when not moving, make it unnecessary to provide for filling it each stroke?

5. If a compression cylinder is used, is it either necessary or desirable to provide any special means of cooling it?

6. What gage wire and what mesh has been found best in a 2-cycle intake to prevent backfiring; that is, which gives satisfactory results with least obstruction?

Answers:

1. No. The separate supply cylinder is common European practice. The crank-box pressure is no lighter and no cheaper than the supply cylinder may be.

2. No; but there is nothing gained by high charge pressure. Whatever work is done in charge compression before the charge is in the working cylinder beyond that sufficient to cause a rapid and complete intake is lost, and worse than lost as the heat must be dissipated.

3. The ideal conditions would place the charge in the cylinder to fill it to the exhaust port, in case of no valves, at the lowest possible pressure, with no notable charge compression at any time. These conditions can be obtained in practice, the temperature of the charge in the cylinder being little above that of the exterior atmosphere.

4. The compression piston displacement need not exceed the working cylinder volume above the exhaust port top line. Charge transfer passages can be made so short as to be negligable. No check valve is needed, as the working piston closes both the intake and the exhaust port at the beginning of the compression in the cylinder. You have the idea of a slightly comprest charge in a charge reservoir, which is practicable, tho probably not the best thing possible.

5. Compression raises the temperature of air rapidly, but a bulk of air, carburized or not carburized, can be transferred to the inside of a 2-cycle cylinder without appreciably compressing the charge, because there is only a very small pressure in the working cylinder to resist charge entrance. Under some conditions there may be less than atmospheric pressure in the cylinder at the time of intake port opening. If the charge is much comprest heat will be imparted to the compressor walls; this heat might or might not be absorbed by the expanding charge or by the next incoming charge.

6. Ask Perry Okey. Okey Motor Car Co., Columbus, Ohio, about wire gauze, precise information not at hand. H. D.

Memphis, Tenn.

I wish to build a two-cycle engine which I intend to make valveless. Would like to make an air compressor or a compressor to take the gas from the carburetor to supply and purge the gasoline cylinder. If the gasoline cylinder is a four-inch bore and four-inch stroke, what would be the size of cylinder for the compressor to furnish the engine with ten lbs. of pressure, or would less pressure do, or would it be better to use a receiver? Or, would it be better to inject the gasoline after the exhaust is closed independent of the air, and about what would be the size of the pump to inject the gasoline which I suppose would have to be regulated by a throttle?

V. BEELING.

If you intend to begin experimenting with the 2-cycle motor you should inform yourself as to the construction of all small 2-cycle motors now made, which almost invariably use crank-box pressure, tho crank-box pressure has nothing whatever to do with the 2-stroke cycle. There is no need of more than a very slight charge pressure if you use a separate supply cylinder, as the intake port is open long enuf to take the charge before it has much compression given to it. The capacity of your compressor or charging cylinder can not exceed your charge space in the cylinder added to the port space between the supply cylinder and the motor cylinder.

You can make your intake port any length you chose, but you must make your exhaust port at least ¼-inch longer than the intake port. The length of port is its up and down dimension in a vertical cylinder. If your port is long enuf to stand open for 90 degrees of crank travel and you work the supply cylinder piston with a crank on the motor crank-shaft, then you will have about 15 pounds pressure on the charge when the intake port opens, but this pressure will fall to nearly nothing as soon as the intake port does open, and will be very small for the remainder of the supply piston stroke.

There are various linkages which can be used to work the supply piston, some of which can be made to supply the cylinder with only a very little charge pressure at any time.

You ask to be supplied with drawings for building a 2-cycle motor. What do you hope for, a new motor better than anything now made? Even if you could obtain such drawings they would be very costly, as they would cover a very valuable new invention, and your motor would be very costly before you were done building it.

The fuel can be injected into a charge of pure air after or before compression. This has been done repeatedly and with complete success, and avoids the carburetor, and this method of fuel supply permits the use of heavy fuels, like kerosene or raw petroleum. Gasolene mixes with air so readily that it has come into common use for car motors, but it is not likely to be retained, as it is extremely dangerous and very costly. Probably raw petroleum will be largely used in motor cars. Some of the mechanical oilers, like the Lavigne, could be made to supply any liquid fuel, governor control, with entire satisfaction. Pump fuel supply is broadly old, covered by an expired English patent.

Perhaps these hints may be of value to you, but you should make a careful and exhaustive study of the 2-cycle motor before you begin to spend money trying to bring out something new.

H. D.

Kendall, N. Y., June 29, 1907.

I should like to have your opinion upon a two-cycle motor of the following dimensions.

Bore 4 inches. Stroke 3⅝. Compression 90 pounds. Intake port 5.28x⅝. Exhaust 5.28x⅝. Intake and exhaust ports separated by one-inch bridges. Intake has 3 bridges 3-16 inches wide. Exhaust has one 9-16-inch bridge cast hollow for air cooling. Cylinders offset ⅝-inch. Cylinder wall ⅜-inch thick. Connecting rod 5⅝ inches long. Shaft bearings 1⅜x3. Crank wrist 1⅜x1½. Bypass through piston and cylinder walls between upper and lower sets of rings. Inlet to crank case by Mr. Malcolm's disk and port. Cooling by pins on cylinder. Air blast from blower to be sent in at top of applied jacket and discharged at bottom just above ports. Also pins cast on under side of piston head. Deflector very similar to Mr. Malcolm's. Aluminum bobs on crank shaft to make case compression about 6 pounds. What power should this motor show at 1300 revolutions? At this speed the motor has a piston speed of 785 feeet which is about the limit for satisfactory lubrication. About what power at 800 revolutions? Which is the more satisfactory method, to cast cooling pins integral with the cylinder or to apply by the Knox method? In the first method better radiation would be obtained, but wouldn't it make an extremely expensive cylinder casting? Can air cooling be used at this compression? 90 pounds is higher by 20 pounds than any air cooled motor that I am familiar with, but I chose this compression because the motor will be run on throttled charge more than half the time, and from recent investigations it appears that high compression under these conditions is desirable while on full charge 70 pounds is high enough. It was the opinion of Mr. Malcolm that compression up to 100 pounds could be used with air cooling. In my design the piston head slopes from the top of the deflector to the bottom of the exhaust port giving ample chance for cooling since the cool gas in the crank case has to sweep across the cooling pins on its under surface. What diameter inlet and exhaust pipes should be used? I am aware that 5⅝ inches connecting rod is considered short for this size of cylinder, but I have adopted it because I believe that the advantage gained by having the ports open longer more than compensates for the angularity. Will you give me some idea what it will cost to build this motor? It will be necessary for me to hire all the machine

THE BUFFALO CARBURETOR

The top notch in carburetor construction has been reached in the BUFFALO for 1908. Those manufacturers who want their new models to be free from carburetor troubles will do well to follow the lead of FORD, WELCH, KNOX, WAYNE, JACKSON, QUEEN, WOLFE and others, and equip their 1908 cars with the BUFFALO.

Some of the Advantages of the BUFFALO

1.—It is a mechanical carburetor, flexible and reliable.

2.—It is economical in gasoline cosumption, saving from 20 to 50 per cent.

3.—It gives complete control of the motor at all times.

4.—It produces greater horse-power per gallon of fuel, consequently greater mileage.

5.—It is not affected by vibration nor atmospheric conditions.

Give it a trial. We know it can convince you that our claims are true.

Buffalo Carburetor Co.

889 Main St., Buffalo, N. Y.

Hosted by Google

work done. Please give approximate cost in dollars. What should be the cost for one motor? What should be the cost in lots of 10? Of 100?

G. D. FORBES.

The ports in two different planes, as shown in the description of the "Atlas" motor car, July Journal, appear to be extremely good, and the arrangement of the exhaust ports in a plane above the plane of the piston and cylinder intake ports seems very good. No special fault can be found with the specifications here given. The rods might well be longer as there is plenty of time to exhaust and take in a fresh charge while the ports are open, no matter what the rod-length is.

With 90 lbs. compression about 270 lbs. initial pressure is to be expected, but as the 2-cycle motor cannot fill the cylinder with the charge you will not have 90 lbs. working compression. No trustworthy estimate of H. P. can be made in advance, by the writer, at least.

You will probably do well if you obtain 100 lbs. average pressure and as the working stroke is 3 ins., you can readily estimate your work on the piston at revolutions specified, remembering that your motor is single acting.

It is cheaper and better to cast your cylinders with integral cooling projections. The cased-in 2-cycle cylinder, cooled by forcing air through the casing, as practiced by Frayer-Milller, was patented in 1844, and nobody holds any broad patent on air or water cooling. Frayer-Miller use 85 lbs. compression and have no trouble. Of course. whatever reduces the charge volume reduces compression if the compression chamber cubic content is always the same, and as most car-motor work is done with the throttle very little opened, it is very clear that the compression must be small. In one case of a very large bore engine something less than 15 lbs. compression, actual, gave the car about 40 miles per hour on a good road. This same car could be run at a slow walking pace, about 2½ miles per hour, on high gear, by close throttling, making it appear probable that the compression was not above atmospheric pressure. This particular motor showed 60 pounds compression by gage, when the cylinder was filled with pure air. The advantages of high compression are (a) to increase the full-charge, and thus give the maximum, power of the motor, and (b) to increase the compression of throttled charges and so obtain as much partial-charge economy as may be.

No reliable estimate of costs can be given The satisfactory way is to go to a good shop without knowing the shop and workmen, for either one motor or for current manufacture. and contract for production of parts to drawings and specifications furnished. You do not give the number of cylinders, but that is not important.

The writer believes. fully. in the 3-cylinder, 2-cycle, air-cooled motor for motor-car driving.

H. D.

A QUESTION OF TWO-CYCLE ENGINE DESIGN.

St. Louis, Mo.

I write to ask you some questions regarding a four-cylinder, two-cycle engine which I am designing. Each cylinder has a seven-inch bore, a six-inch stroke and a two-inch compression space at the head of the cylinder. The engine is for automobile work. and I am building it as light as possible. How thick should the cylinder walls be? How thick should the cylinder head be? What fraction of the area of the piston (which is about 38½ square inches) should the area of the intake port be to get the most power out of the motor? How far above the piston when it is at the bottom of the stroke, should the bottom of the intake port be? What part of the area of the piston should the area of the exhaust port be to get the most power out of the motor? I intend to compress the gas first, in the crank case. How many pounds or ounces to the square inch should this compression be? How large a crank-shaft should I use if I made it out of the best nickel steel? What horse-power would this motor give at 600 R.P.M.? I mean, how much H. P. would all four cylinders give? I would like to be able to run the motor 900 to 1000 R.P.M. under a load. Can this be done? If the parts were the right size, how much faster, if any, would the motor run under a load? How far above the bottom of the piston stroke should the bottom of the exhaust port be?—F. VAN BLARCOM.

I assume that your motor is for a passenger car. As you intend to use the two-stroke cycle you do not need four cylinders. Three cylinders will give you a smooth action. 7x6 inches is altogether too large for even three cylinders. 6x5½ is as large as you have any use for, even for a very large car. Three 5 or 5½x5 ins. will give you all the power you can use. The cylinder walls should be 5-16 to ⅜ thick. Head thickness depends on the construction, whether integral water jacket or applied head, and so on, and the form of applied head. A head ⅜ thick, suitably ribbed, will do for 5 or 5½ bore cylinders. Your cylinder head must resist at least 300 lbs. to the square inch.

Give all the port area you can. Port dimensions have nothing to do with anything but the motor speed. The more port area you have the faster your motor can run. Place the ports in two planes as in the "Atlas" motor, Journal, July, Page 81, or "Heerman," Page 166. The greater the port dimension is lengthwise of the cylinder, the more time you have for charge intake. The exhaust port should be open at least ¼ inch, and ⅜ is better, while as much as ½-inch would do no harm before the intake port opens. Do not consider port area at all, with reference to piston area. Port area and piston area have no functional relations in the two-cycle motor. Say you open your exhaust port, with a 5-inch stroke, when the piston has made 3¾ ins. of the working stroke, and open the intake port when the piston has made 4⅛ ins. of the 5-inch working stroke. Pay no attention to pounds of crank-box pressure, simply make the clearance as small as you can. Apply filling pieces to your crank-arms and save all the clearance you can. Do not use a nickel steel shaft. A good 40-point carbon steel forging is good enough. Make your shaft not less than 2¼ dia., wrists the same, and 2½ dia. is better.

With three cylinders, 5½x5 ins., you should show 50 or 55 H. P. at the very least at 1000 R.P.M. Your motor should be strong at 1500 R.P.M. The more load the slower the motor will run, of course.

The bottom of the exhaust need not be anything above the piston at low point. or it may be. say, as much as ½-in. above. The exhaust port ought to be big enough. A compression chamber for a 5-in. cylinder, 5 ins. stroke, may be 5⅛ diameterx⅞ high. If you apply your piston heads you can vary the compression chamber to suit yourself, by trial. Before you go on with your design you will do well to study the Okey 3-cylinder 2-cycle motor—H. D.

QUICK WORKING STROKE AND SLOW RETURN.

J. J. McC. has been giving thought to the 2-cycle motor, and having concluded that the working stroke should be as fast as possible made application for a patent on the linkage shown in the illustration, J. J. McC., 2-cycle motor.

The effect of this well-known linkage is to make a driving crank move the free end of a slotted lever turning on a pivot at one end move much more rapidly during one part of the movement of the uniform velocity crank, than during the other part of the crank revolution.

A, A, A, cylinder and crank-box, integral. B, piston. C, connecting-rod. D, crank-wrist circle of travel. E, crank-wrist. F, F, slotted lever, pivoted at G, to the crank-box. H, piston-pin. I, connecting-rod joint to the slotted lever, F. F.

The arc MN, struck from the center of G thru the center of the crank-shaft, divides the circle, D, unequally, by cutting D at X and V, thus making the up-stroke of the piston in the crank-time represented by the larger angular advance, YDX, and the down-stroke, working, in the crank-time represented by smaller angular advance, XEY. This linkage makes the piston

REO 1000 points

The only perfect one at the price

Out of 80 starters and 50 finishers in the last great Glidden Tour—except for the Premier, the REO $1250 Touring-car was the only car at less than double its price, with a perfect score.

All the others cost from $2500 up to $7500. And many at similar prices dropped out entirely from this gruelling contest.

The same car immediately started on a non-stop run to Jamestown, Va., a distance of over 350 miles, making the trip in 23 hours. The car is now on exhibition in The Transportation Building at the Exposition.

When you can buy such perfect performance for $1250

Why pay two or three times the money?

Write for the book which tells you how the REO does it.

Digitized by Google

slow in the compression stroke and fast in the working stroke, which is of some theoretical advantage.

This linkage is commonly seen in slotting and shaping machines.

But the designer desired to obtain a quick working stroke with a slower return and compression stroke for the 2-cycle motor piston, hence the uniform velocity crank is made to turn in the direction shown by the arrow in the figure, which gives a quick down stroke of the piston with very great increase of piston velocity at mid-stroke. This action also increases the time of piston port-passing, so that the exhaust and intake times are somewhat augmented.

This linkage is thus seen to increase the speed and shorten the time of the working stroke and to increase the port opening time; these conditions are favorable to the action of a 2-cycle motor when considered merely as a heat engine.

When considered as a mechanical linkage in motion, this distortion of time and speed is very bad. The piston and connecting rod must be stopt and started twice in each revolution of the crank. A crank does not give the very best acceleration and retardation time, but it gives a very close approximation to the best time, much closer than any other equally simple linkage, and for this reason has never been displaced for the purpose of changing reciprocating to rotatory motion.

Again, the slotted lever and sliding box is

AUTOMOBILE TRADE JOURNAL

difficult to make, and very difficult to maintain, and the introduction of the slotted lever largely increases the number of parts in the 2-cycle motor, as well as the weight, the cost and the space occupied. If crank-box pressure is used to supply the cylinder charge the crank-box clearance should be as small as may be and here again the lever is bad, since it requires a larger crank case.

Once more, almost the same differences in the times of the two piston strokes can be had by offsetting the cylinders, without adding to the number and cost of the motor parts.

Viewed as a working machine only, it is vastly better to make the two piston strokes in the same time, and to use a long connecting rod so as to distort the crank-time acceleration and retardation of the piston as little as may be.

No difference how right or how wrong, the simple and smoothly working machine will always be preferred to the complicated machine which has violent changes of part-velocity, and hence is harsh in action and difficult and costly in maintenance.

These considerations make it easy to see why both Otto and J. J. McC. saw advantages in this slotted lever 2-cycle motor action and why the Otto patent never came into general use.

This slotted lever motor is shown here and considered at some length because the idea has been advanced often, and is probably even now thought valuable by many persons to whom it is new.

J. J. McC.'s story is here given in his own words. The reasoning is right, but the machine itself is wrong, and so far wrong that it is of no use at all when compared with the ordinary form of trunk-piston, 2-cycle motor.

J. J. McC. writes as follows:

"Hugh Dolnar:

"Several months ago I applied for a patent on a device, a crude sketch of which I enclose, which I believe will be of value to any manufacturer who takes it up. I had an examination made of the Patent Office files for 25 years back and found nothing of the kind in sight, and I believed I had something new.

"Judge of my surprise when my application was rejected on an old patent to Otto, dated December, 1873, about 33 years ago.

"Now, what puzzles me is this: Here is a device that will improve any engine it is fitted to. It has been public property for years. Competition among manufacturers should cause the adoption of anything and everything that will help their product. Nevertheless, I am unable to find any engine on the market to-day using this simple device.

"Now comes the query: Are the manufacturers really fit for their business, or was I wrong—and was Mr. Otto wrong in thinking this device an improvement on the ordinary style of crank motion for gas engines? Being unable, after badgering my brains for months, to discover any flaw in my argument that this is a valuable feature, particularly to the two-cycle engine, I have decided to ask you and if you can see your way to answer me in the columns of the 'Journal' I think a good many people will be interested in what you say.

"My main idea was to reduce the working temperature of the engine. I claim that the quicker expansion of the gases, due to the accelerated working stroke not only reduces the temperature, but does it in the only profitable way by using the saved heat to push the piston instead of heating up the surrounding atmosphere.

"There are incidental advantages, however, that are not to be despised, viz.: the increased time allowed at one end of the stroke for the admittance of the new charge and the escape of the old one, and at the other end to permit of greater advance of the spark without back pressure and consequently more complete combustion at the beginning of the stroke, and the reduction of the side-wear on the piston and cylinder, due to the small angle of the connecting rod.

As I have already stated this shortens the stay of the heated gases in the cylinder, and the cooling period is correspondingly prolonged. Will not this result in a lower working temperature? Then we have a more rapid rate of travel for the piston at the beginning of the stroke, due to the fact that the stroke does not commence until after the crank-pin has passed the 'dead point' by about 30 degrees. Will not this tend to relieve the strain on the engine at the moment of explosion, and reduce the chances of cracking the cylinder?

"I could ask 20 other questions about this device, but this letter is already much too long, and I will simply go back to my original query in effect: 'Why is this idea allowed to sleep in the Patent Gazette instead of being put to use?

"Respectfully,

"J. J. McC."

First of all, J. J. McC. should have gone back much more than 25 years to cover the gas engine. The first American patents on gas engines, 2-cycle, were granted in 1844 and 1846, and covered air-cooling, water-cooling and the use of hot-tube ignition, and wholly anticipated both Lenoir and Daimler. These patents are never spoken of, tho they are important.

Secondly, charge-firing is slow, and there is no violent shock by explosion due to charge ignition. In the third place ignition demands as much time as possible, and altho this linkage if of value, it is not of enuf value to make up for its bad features.

In conclusion, altho this linkage is not good, many persons think it is so, it is here noticed at some length. H. D.

HAYNES

Always Has a Perfect Score.

THE GLIDDEN TOUR that left many cars by the wayside, proved the perfection of the Haynes, which finished with a **perfect score.**

THE CHICAGO SEALED-BONNET NON-MOTOR STOP RUN. All four Haynes cars finished with **perfect scores,** tying for first place with cars of twice their cost.

THE NEW YORK SEALED-BONNET CONTEST. A Haynes won a **perfect score** and is still running with seals intact.

THE NEW YORK MOTOR CLUB ENDURANCE RUN to Albany was a decisive Haynes victory, and the record of the Haynes stock model in the VANDERBILT CUP RACE is still unsurpassed in automobile history.

Private Haynes owners are constantly making **perfect scores.**

The man who brought back his car to us after he had run 5000 miles without an adjustment or mishap thought that the behavior of his car was extraordinary and deserved investigation. We assured him that his case was not exceptional—the exceptional case is that of the Haynes which gets into the repairman's hands.

There are reasons, and good ones, for such reliability—they lie in the design of the car—free from complications—and practically trouble-proof. Crank the engine—throw in the clutch—and go;—there will be no tinkering or fuss—no delay on the road.

The Haynes is made that way; it is "the car that always has a **perfect score.**"

The Menges Motor Car Company, Grand pids, Mich., U. S. A., will offer for the ason of 1908 two models of chassis, one cylinder with a tonneau body to seat 8 ssengers, all facing front, and the other, aller one, 6-cylinders, fitted with either 5-passenger tonneau body, or with a 3-ssenger roadster body.

The Menges Company, $300,000.00 capital ck, is at the date of this writing, July 1907, just completing its organization.

The two Menges 1908 models embody iking novelties at almost every point, and e among the most original examples of 08 motor car designing.

Only the 4-cylinder, 8-passenger, touring r is now on the road; the new 6-cylinder r, seating 5 passengers, is nearly com-eted, but is not here described in its de-ls, which will bear a general resemblance the corresponding elements of the 4-cyl-ler, 8-passenger car, here shown and de-ribed for the first time.

that no change gears are provided save the reverse and the low speed.

Menges has made reversing gas-engi but prefers the toothed-gear reverse quick handling. The cars have abund piston area for all work on hard road s faces, but no matter what cylinder diame is used, a low gear is required for d mud and sand. The pistons are 6⅛ i diameter by 5½ ins. stroke, with alumin motor-base and oil pan, base lugs reach across to chassis frame brackets and carr on short coiled springs, interposed betw the motor-base lugs and the chassis fra bracket members. The weight of the tire motor is about 600 lbs., and this spr support of the motor on the chassis fra has been very carefully worked out, so to carry the motor with the least probabi of undesirable shock on the prest st chassis frame sides which are of the us 3-16 thickness. The motor valve stems vertical, valves in cages in the cylin

An Exciting Race and a Close Finish.

It is a remarkable co-incidence that after many months of hot competition, with honors alternating, on the first day of August, 1907, exactly the same number of Model C and Model D Jackson Cars respectively, had been sold and delivered, and the race was still on, with the unfilled orders slightly favoring the Model D. We are pleased to present pictures of the contestants.

The Model C Jackson

Price $1250. Two cylinders, horizontally opposed, under the body. Chain drive, with a strong and noiseless chain. Horsepower, 24. Wheels, 30x3½. Five passenger body with detachable tonneau. Complete equipment.

The Model D Jackson

Price $1500. Two cylinders, horizontally opposed, under the hood, giving much of the effect, in looks of a four-cylinder car. Horse Power, 24. Bevel-gear drive. Wheels, 32x3½. Ample seating capacity for five persons. Complete equipment of horn, lamps, etc.

manner.

MENGES' SELF-STARTING.

The self-starting device on this car con-
sists of an ordinary electric motor geare
down to 18 to 1 by 8 d. p. spur gearing t
a large gear 1¾ ins. face, formed of a stee
ring of gear teeth fixt to a grey iron wel
and hub, and mounted on the line-shaf
close to the clutch. A one-way clutch o
four steel rollers, ¾ dia., in eccentric seat
is used in the gear hub. Current to driv
the electric motor is taken from the storag
battery, and the start is very simple, chea
and certain. The motor crank-shaft is fitte
with the ordinary starting ratchet in fron
and a starting crank is provided for con
venience in the factory, but on the road th
starting crank seat is covered with a screw
cap and no use whatever is made of th
hand-start. The electric self-start is ex
tremely convenient, as it can be used t
drive the car on the factory floor or eve
for short distances at slow pace on th
street, since the motor consumes very lit
tle current. The starting motor weighs 1
lbs., and this first one, made to specifica
tions cost only $30.00. The motor arma
ture shaft normal speed is high, but th
motor has a built-in, planetary speed-reduc
tion of 2¼ to 1, making, with the 18 to
speed-gear reduction over 40 to 1 reductio
from the armature shaft to the motor crank

Menges 1908 Car, left side of motor in complete ca
showing the oil box, oil piping, water pump and ex
haust pipe. Note the easy curves of the exhaust mani
fold. The hand-operated plunger oil pump on th
inside of the front board is piped to force oil into th
hollow piston pins as the cranks pass the lowe
centers. The water pump is centrifugal. The oilin
system is hybrid, over-flow and return for crank
journals, scoop for crank wrists, oil-mist for th
pistons, and hand pump at discretion, oiling for th
piston pins.

lected to the starting pinion by a one-
roller and eccentric-seat friction-clutch,
the strap-drum is also provided with a
return-winding spring, so that by pull-
the strap-ring upward the starting pin-
will be turned and so give a hand-start-
action for the motor; the reduction is
1. A push-button switch in the front
of the driver's seat, near the right-hand
gives storage battery current to the
ting motor. If the motor fails to start
antly it can be helped with a pull on the
l strap, the one-way clutch permitting
motor shaft to over-run the drum, and
n the strap-ring is released the drum
ng automatically winds the strap close on
drum and holds the strap ring in place
l against the floor. Thus the Menges

changed. The front wheels and floating rea
axles are on Timken roller bearings.

The gear changes are made by shiftin
two double-ended, solid-jaw clutches whic
are worked by latched hand levers thru roc
shafts working blocks having coiled spring
on each side, so that the hand lever may b
at once placed at the desired control-notc
whether the clutches are in position for en
gagement or not, and as soon as the clutc
jaws move to engaging position the sprin
forces them into place, so that any contr
engagement can be made at any time, wit
out delay and without clashing of the clutc
jaws. Since all the gears are always ful
engaged, there is no possibility of damagin
the gear-teeth by mishandling.

Menges 1908 Car, right side of motor complete. This engine is controlled by the time of closing o
e inlet valves and not by an ordinary throttle. When running with small compression the charge expelle
m one cylinder can be used in another. The charge check-valve is in the casing at C, and prevents th
placed charge from passing to the carburetor, thus forcing the charge displacement to pass to the cylin
which is drawing in a charge. The steering gear is a right and left thread screw action. The fan i
ball-bearings and is gear driven, all gears being inclosed.

really has three starts, one by the elec-
motor, a second by pulling on the leath-
trap from the seat and a third by simply
ssing the motor-switch push-button. The
linder motor starts so invariably on the
k that it is a rare occurrence to be
ed to resort to the electric self-start,
ch can be driven as a dynamo and made

USE AND TREATMENT OF SPRINGS.

Menges places springs in many unusu
positions, preferring spring support to rig
support wherever flexibility to a limited e
tent can reduce shock. He splits l
reach chassis frame springs in tw
lengthwise placing one-half of each sp
spring on each side of the symetrical re

A WORLD'S "RECORD" BY

STEVENS-DURYEA BIG SIX

REGULAR STOCK, REGULAR GEAR

At the races given by Lowell, Mass., Automobile Club, in July, the STEVENS-DURYEA BIG SIX with touring car body and containing seven people, traveled a mile on the rough road in 51 seconds flat. This equals 70¾ miles per hour and establishes a world's road record.

The same car went 5 miles in 5 minutes on a very narrow road which had numerous short curves besides. The car was compelled to avoid a wreck in middle of road thereby losing some seconds in time.

The regular stock BIG SIX, stripped, covered a mile in 46½ seconds, equalling a rate of 78 miles per hour.

A telegram from F. W. Eaton, Delmonte, Cal., states "BIG SIX just off freight car. Made fastest 5 miles at Delmonte track today, five forty-four and half."

STEVENS-DURYEA cars lead from "ocean to ocean."

is now certain that the Menges 4-cyl-
ler motor, here shown, can drive the car
m a slow walking pace, about 2½ miles
hour, up to a very high speed, prob-
y 65 or 70 miles, on the high gear, with
changes save those made by sliding the
n-shaft endwise to vary the closing time
the intake valves.

t is also certain that the four rear
ings give a very soft and easy support
the tonneau.

LARGE PISTON AREA.

Menges assumes that the piston area
ould be sufficient to do all hard-surface
d work on the high gear, hill climbing
luded, and that the low gear should be
ed for low speeds necessitated by sand
d mud, only. The Menges four cylinders,
x5½ ins., are, so far as the writer's
owledge goes, the largest shown in any
e touring car. But the motor weighs
ly about 600 lbs., which is not excessive.
r all ordinary good-road work the in-
e valves are held open until the piston
within about 1¼ ins. of the end of the
mpression stroke, which gives something
s than 15 lbs. compression, with a very
ge expansion and of course low terminal
essure and temperature. With this small
ction of a full charge the car makes 40
45 miles with great ease and smooth-
ss of motor action.

BRAKES AND CONTROL.

The car has external and internal rear
b drum brakes. The internal brake-drum
12 ins. dia. by 2½ ins. face. All brakes
e worked thru equalizers, and both brake-
oes and brake bands are faced with
andy belting.

Jump-spark plugs only were fitted to the
r when the accompanying illustrations
ere made. The spark and charge volume
ntrol levers are on top of the steering
heel, and there is also a small horizontal
ccelerator" pedal at the extreme right of
e foot board, which opens a throttle
lve between the carburetor and the intake
ping. The right-hand vertical pedal ap-
es the internal ordinary brakes to the
ar hub brake-drums. The left-hand verti-
l pedal operates the clutch, and is inter-
kt with the carburetor, as previously
entioned.

There are two plunger pedals, in the rear
the brake and clutch pedals. The right
e engages the starting pinion and spur
ar, by a linkage including an eccentric
rangement which disengages the starting
nion and the starting gear. The left
unger pedal is deprest to pull the cam-

bulk of charge with a compression pr
sure of about 15 lbs. gage. The cylin
bore is 6⅛ ins., and the dome-shaped co
pression chamber diameter is 6¼ ins. Wh
the cylinders are filled with cold air
maximum compression is 60 lbs. T
muffler is cut out by a small pedal.

The hand oil pump oils the piston pi
when the pistons are at the bottom o

Menges 1908 Car. Control. Caption in text.

of their travel. The outside hand lever
plies the internal emergency brakes by
pull and at the same time disengages
clutch; this lever is latched at both
tremes of travel. The middle lever
latched in 3 positions; extreme forward
sition gives low gear, extreme rear p
tion gives high gear and mid-position
engages all gears and leaves the car
for coasting.

The inside lever is latched in three p
tions, extreme position forward gives
reverse; in extreme rear position this
side lever gives low gear forward; w
latched in the middle the car is free
coast. The rear axle change gear gives
car two speeds forward and a reverse,
is made at Columbus, Ohio, by the "Di
Drive" Axle Co.

BEAUTY OF DESIGN.

The outlines of this Menges car body
highly satisfactory in points of symm
and proportion, the car as a whole form
a fine example of the straight line t

ON THE ROAD.

The writer had no opportunity to m
a long run on this car, nor to make
measured fuel runs. One run of 40 or
miles showed the control by varying
valve-closing time to be extremely pro
and flexible. The car is very still, and

ANNOUNCEMENT
TO SPARK PLUG USERS

A Money-Back Guarantee
WITH EVERY
DIAMOND SPARK PLUG

The ONLY Plug which you can LOOK THROUGH and SEE THE SPARK in the cylinder

¶ Believing that proof is better than argument and that practical demonstration is the ***best*** proof, we make the following unexampled offer to Spark Plug users:

Send us $1.50 (Marine Engines $1.75) for each Spark Plug desired, in check, money order, stamps or cash, together with name of your car or engine, and we will send you, PREPAID, Diamond Spark Plugs to the amount of your order and under the following absolute

GUARANTEE

If within six months of date of purchase you are not entirely satisfied with the Diamond Spark Plug in every particular, write us to that effect, and the purchase price will be returned without question or quibble.

¶ Diamond Spark Plugs are made from the highest grade material throughout. The porcelain used is unbreakable, all metal parts nickeled and polished and cannot rust.

¶ There is no short circuiting. No packing to blow out. No cement or shellac used. The sparking points are non-corrosive throughout.

¶ These and other features make the Diamond Spark Plug a ***serviceable certainty.***

¶ Send to-day, while the offer is fresh in your mind, for your first perfect Spark Plug and end your sparking troubles.

the exhaust side at the top and running
t at the intake side. This prevents dis-
rtion from heat and relieves binding and
cessive wear on certain spots in cyl-
ders.

LUBRICATION.

Each cylinder has individual lubrication,
ere being a compartment for each cylin-
r into which oil is forced by a mechani-
l lubricator located on the dash and steel
lt driven from the rear of the cam shaft.

the nozzle and mounted on binnacle piv
keeps the level in the nozzle the same
any angle of the car.

CHANGE SPEED GEAR.

The transmission is driven thru
conical leather-faced clutch with adjusta
inserts to insure easy engagement.
tween the clutch and transmission there
a floating or universal joint, which preve
any lateral thrust on the bearings cau
by twisting of the frame on uneven roa

A selective type transmission, with f
speeds ahead and direct on third, give
good serviceable gear for moderate sp
capable of handling all usual road con
tions, while the special or high gear
be used for bursts of speed without rac
the engine. Hess-Bright bearings
chrome nickel steel are used thru
the transmission.

Both universal joints are set at the sa
angle, as in this position the second jo
corrects the irregularity of motion cau
by the first, giving a much smoother dr
than joints set in the usual way.

Both service and emergency brakes
mounted on the rear wheels, there be
an air gap or cooling space between
two. Collectively there are 338 squ
inches of braking surface, so that the
can be handled on long down grades wi
out heating brake drums.

Cost of Maintenance

There is much talk of operating cost, some fact, more fiction.

Mr. E. S. Gerling, who is a man of method and details, has kept an accurate account of the running expense of his Rambler Type One and furnished Mr. W. K. Cowan, from whom he purchased the car, with the appended statement of maintenance. It speaks for itself.

LOS ANGELES, CAL., July 3, 1907.

I, E. S. Gerling, of Pomona, Cal., purchased a Surrey Type One Rambler, in 1906, from W. K. Cowan, of Los Angeles. Covering a period of nine months from date of purchase, my car ran 3750 miles. I kept a strict account of all expense to machine and tires, also gasoline, lubricating oil, waste, polishing material, and in fact every item of expense and up-keep connected with the machine, including in this expense the cost of gloves. This total expense at the end of nine months mentioned, amounted to $1.05 per 100 miles, making a total of $39.37, this being absolutely the total cost to me in money of running this machine 3750 miles, and covering a period of nine months.

I certify that the above is correct.

E. S. GERLING.

Subscribed and Sworn to before me this 8th day of July, 1907.

J. A. GALLUP, Notary Public in and for the county of Los Angeles, State of California.

7 cars each season, now, however the of a lot of eighteen cars are on the l for their try out. The change in tac- followed the reorganization of the com- y and its capitalization at $200,000, a -story factory having been secured at th Bend, Ind., in January, 1907.

being united by bolting together the integr flanges. This construction permits of r moving one-half of it or two cylinders wit out molesting the other half. The accon panying cut Fig. 2 illustrates half the ca shaft and one-cylinder with the valve hou ing removed and the parts lifted somewh

g 1—Plan of 1908 Tincher Chassis, showing the arrangement of the motor, change speed gear, jac shaft, oil and 32-gal. gasoline tanks.

many changes have been made that e familiar with the previous models ld hardly recognize the car. Krupp C. teel is used extensively thruout the con- ction and this has had its effect in the ged appearance of many of the parts.

ne car is a large 7-passenger machine, l with a 50-60 H. P. 4-cylinder motor of h bore by 6-inch stroke. The drive is ide chains, the wheel base is 127 inches 36-inch wheels, with 4-inch front and h rear tires are used. A double igni- system of battery and imported mag- are employed.

SPECIAL FEATURES.

n overhead cam shaft cut from solid N. steel with integral cams and end ges is used. A single cam operates the ke and exhaust valves of each cylinder. er novel features are the 6-inch band h, the peculiar mounting and driving of magneto. Chrome steel is used for crankshaft, change speed gears, cam- t and in the frame. The valves are 35 cent. composition of nickel steel.

most every part of the car is made at factory, a large number of the parts g cut from solid C. N. steel stock vn as E. F.-60.

THE MOTOR.

llowing Tincher practice this 50-60 H. notor has its cylinders cast separately small integral valve chambers on op- te sides in the top of which the valve

from the cylinder head showing their rel tive positions. The flanged end is for a taching the other half and at the other en to a similar flange is attached the bev gear which drives it. It carries two cam A and B. A operates the valves of th cylinder shown and B the valves of th

Fig. 2.—Tincher Cam and Valve Action—This lustrates the top of one cylinder with the val cages, cam shaft and other parts raised up o of position. The single cam A operates the roll arms E and F, which are rigidly connected to arm C and D, which give the valves their ½-inch ope ing. The shaft of F passes thru the hollow shaft E. The other cam B operates in a like manne both valves of the next cylinder. This mechanis is enclosed in an oil-tight aluminum case. The e haust operating arm E is fitted with two rollers

Here is a plain reason why

Morgan & Wright Tires

Are growing in favor

In a recent issue of the India Rubber World the following pertinent observation was made respecting tire-selection:

> "What does A or B or C care who makes his tires, or how he makes them, so long as they render a service, for which he cheerfully pays, whatever is charged. He asks simply that the tires will take him out, and home again, without accident.

That's good, sensible talk. The automobilist simply demands protection against those mishaps for which tires of too little strength are responsible (obviously no rubber tire could be made that would wholly eliminate accidents from without). And the motorist will naturally favor the tires that give him this protection.

MORGAN & WRIGHT TIRES are enjoying an unprecedented sale (a larger percentage of increase over last year's sales, we believe, than is true of any other make), and we have plenty of evidence on hand to warrant the conviction that this demand has been created solely because the tires have demonstrated—to manufacturer and dealer and car owner—that they provide the kind of protection referred to in the article quoted above.

WE MANUFACTURE A FULL LINE OF BATTERY JARS AND ACCESSORIES OF A 1 QUALITY. SEND SPECIFICATIONS AND GET OUR QUOTATIONS. . : : :

"No Speedometer in the world ever had such rapid and violent testing."

—S. F. EDGE.

The most remarkable record ever made. S. F. Edge, in his Napier Cars, traveled 1,581 miles 1,310 yards in 24 hours, averaging 66 miles per hour. During his phenomenal ride he governed his speed by the use of the Jones Speedometer. Read what he says:

"The Jones Speedometers were simply invaluable; in fact, for a long distance ride on the track one could not do anything like as well without such a splendid and reliable speed recorder as the Jones. I would never be without one when running on the track."

"I think no Speedometer in the world ever had such a rapid and violent testing, and they all came through perfectly."

The cable revolutions per hour at a 66 mile speed total 168,300, or 4,039,200 in 24 hours. A most remarkable demonstration of the Jones "staying" qualities. Not another speed indicator in the world could have lived through this test.

There are more Jones Speedometers in use to-day than all other makes combined. Look on the cars and see.

Last year the Warner Auto-Meter was used on 38 out of 62 Cars entered for the Glidden Tour.—Of the 13 Cars that finished with perfect scores 10 had Auto-Meters on their dashboards—Read the other side for our 1907 Record.

BECAUSE

THE WARNER AUTO-METER is recognized by most experienced Motorists to be the most reliable under all circumstances to accurately tell "How Fast" and "How Far" —no matter how rough the road or weather and no matter how fast or how slow you are driving.

There are good reasons why the Auto-Meter is always to be found on the great majority of all cars in all speed and endurance and reliability contests.

For the same good reasons—not "luck" —you'll see Auto-Meters on at least 90 per cent of all the cars that pass you on the street. Watch the dashboards and you'll see that this is so.

If you put an Auto-Meter on your car you'll enjoy double the pleasure of automobiling—and say so yourself when you do.

Let us tell you all the good reasons why.

This year the Warne Auto-Meter was use on 55 out of 74 ca entered for the Glidde Tour.—Only 19 of a other speed and di tance indicators we used on the other car —Very Good Reaso for this showing.

planetary two-forward speeds and a reverse drive, and requires two exterior friction bands, but is wholly without toothed-gearing, whence the name "Gearless Transmission." As the speed-change selection is made operative by friction-band application any desired change can be made at any time. The reverse drive is at a somewhat higher rate than the low forward speed.

This Gearless Transmission has the great advantage of no change-gear friction whatever on high-speed, rolling friction engagement in the low-speed and reverse, with no tooth-friction since there are no gear-teeth, and perfectly silent action, and is ideal in handling, any change being possible under any and all conditions.

dered. Weight 3150 lbs., tanks filled. Price $3500, including 5 lamps, mats, horn and tools, ready for touring.

This "Gearless Greyhound" is a design with many novel features besides the gearless speed-change. The very long hood covers two front-boards. The gasoline tank is carried between the two front-boards, and the hood also covers the Gearless speed-change, which gives direct drive, low-speed and reverse. The six cylinders are each 4 13-16 ins. bore and 5½ ins. stroke. This car can make all the speed any gentleman driver wants on the road and is silent and very easily controlled. This Gearless Greyhound is an attractive model to the large class of motorists who want a car that looks like speed and can

Fig. 3. Cross-section of the Gearless Transmission. See detailed explanation in text.

The Gearless Transmission 1908 cars are all large and powerful machines, having all the speed and hill-climbing powers which any motorist can ask for. All the "Gearless Transmission" motors are fitted with double ignition systems, two jump-spark plugs in each cylinder, with storage battery and Bosch magneto current supply.

The Gearless Transmission 1908 4-cylinder 5-passenger touring car is very similar in general appearance to the 6-cylinder car. Its wheel base is 126 ins., gage 56 ins., tires 36x4 front and 36x4½ ins. rear, motor four water-cooled 4-cycle 5x 5¾ in. cylinders, showing 60 H. P. at 1250 R. P. M. There are two forward speeds and a reverse, tonneau body, side doors, swinging to rear, to seat 5 passengers, two revolving chairs added in tonneau if or-

live up to its appearance when called upon to do so.

The Gearless Transmission cars have long wheel bases, large wheels and powerful motors and brakes. Two of the models, the 7-passenger touring car and the 3-passenger "Greyhound" have six-cylinder motors, cylinders 4 13-16x5½ ins., while the 4 cylinders of the "Model 60" are 5x5½ ins. The axles are by Weston-Mott, ball bearings in front and Hyatt rollers in rear, and the steering is by a screw and nut, Elyria Company. The ignition is double, two jump spark plugs for each cylinder, with storage battery and Bosch magneto.

The distinctively novel feature of the "Gearless" line of cars is the friction speed-change, which uses five large cone-

means of the ordinary, pedal-actuated
cone sliding on the clutch disk hub to op-
erate the cam-rocker lever and so expand
the clutch-shoe. As this clutch-shoe is
internal the cam-rocker arm is made with
two members to neutralize centrifugal ac-
tion, and a strong closing spring, not
shown, is applied to hold the jaws against
opening and causing the clutch to drag at
high speed when the clutch cone is in for-
ward, non-engaging position. The clutch
shoe runs normally free from its surround-
ing clutch-cup, internal cylindrical sur-
face, but the shoe is forced into driving
engagement with the cup by sliding the
clutch cone to the right. The clutch cone
is fitted to slide freely on the outside of
the hub of the clutch disk. The driving
cone is fixt to the tapered rear end of the
crank-shaft by means of a large filister-
head screw and a Woodruff key; the cone
hub is bushed with "graphite" anti-friction

Fig. 4. "Gearless Six.," chassis plan. Neither struts nor torsion arm are placed in this large,
vy and powerful car. There is but one universal joint. Two fuel tanks are fitted, one in the
, as shown, 17 gallons, and one under the driver's seat, 15 gallons. This gives 32 gallons of
at least 300 miles range, tanks full. The chassis frame greatest depth is 5 ins., and the width
4 ins. rear and 32 ins. in front. The axles are Weston-Mott, front wheels on balls, rear axles
Hyatt rollers. The rear axles are semi-floating. The springs are half-elliptics, 39x2 ins. front,
aves, banded, jointed in the rear and linked in front. The rear springs are 50x2 ins., 8 leaves,
ded, jointed in front and linked in the rear.

e friction-rings, jointed, only one of can be engaged at one time.

EARLESS TRANSMISSION ACTION.

shown in Fig. 4, with both friction- free and the solid-jaw clutch in neu- osition and with the expanding clutch- lisengaged, the car is free to coast, ut turning any part of the assembly , save the sliding clutch, which is l to and turns with the line-shaft.

LOW-SPEED.

solid-jaw clutch is moved to extreme pulling the inside hand lever. This the ring of caged rollers to make urns with the line shaft and if the shaft is turning and the friction band ied to the driving cup by pushing the pedal, then the turning of the driving cone will cause the cone rollers to run around in the driving cup carrying the cage rings, the cage ring clutch and the line shaft with them. The diameters are such that the line-shaft, in this low-speed forward combination, makes one turn to three turns of the crank-shaft.

HIGH SPEED.

With the low speed engaged, pressure on the left pedal releases the driving-cup friction band, leaving the driving cup free to turn, and the left pedal is pushed forward to expand the clutch shoe and engage the clutch-cup with the crank-shaft, and the whole transmission then turns as a unit at crank-shaft speed, with no internal friction of the transmission parts on each other.

d extreme, which moves the solid-jaw
ch to extreme right position and locks
driving cup to the line shaft, so that
e two members move as one; then the
t, or reverse, pedal is pushed forward,
ying the exterior friction band to hold
clutch-cup stationary. Then the turning
ne driving-cone fixt to the crank-shaft,
es the rollers to revolve in the opposite
ction on their axles and transfer the
on to the larger-diameter driving-cup,
h conveys a reduced reverse motion to
line-shaft thru the solid-jaw clutch by
h it is lockt to that shaft.

CONTROL.

The steering action is a screw and trunio
nut. The spark and throttle levers are o
top of the steering wheel. There are tw
outside vertical hand-levers. The outer on
is latched, and is pushed forward to simu
taneously apply both the external and inte
nal rear hub-drum brake shoes.

The inside hand-lever, also latched, move
the solid-jaw clutch to its 3 positions fo
low speed, neutral and reverse.

There are 3 vertical pedals, the left on
is pushed forward to engage the clutch, th
middle one is pushed forward to obtain lo

Fig. 9. The whole Gearless transmission and control linkage is very large, strong and sub-
tial, giving expectation of long life and reliability. Nothing spared to make the control ac-
s certain, and the very large diameter and great width of the friction bands permit the trans-
sion to be used as the ordinary brake without wear or injury. The friction bands are bronze,
are fitted metal to metal to the steel driving cup and clutch cup exterior surfaces. See text
head "Brakes." The control is most simple, very easily learned and not likely to be mis-
dled.

BRAKES.

ere are exterior and interior rear-hub
-brakes, internal shoes metal to metal,
cup and bronze shoes, exterior band
ly-belting faced, which are all four
ed thru eveners at one and the same
by pushing the outside hand lever
ard. This combined external and inter-
ear-hub brake resistance is ample to
the rear wheels, and is the emergency
action.

THE SERVICE BRAKE.

is effect is obtained by pushing the

speed and the right pedal, when pushe
forward, holds the clutch cup still to giv
the reverse.

ON THE ROAD.

In the afternoon of August 14, a 4-cylin
der Gearless "Model 60," Mr. Breyfogl
driving, an invited friend and one of th
Gearless testers in the tonneau and th
writer as observer, left the Gearless Fac
tory, Rochester, and was driven to Batavi
by the long road, 41 miles, and back fro
Batavia to the factory by the direct road, 3
miles, 79 miles total.

Timken Roller Bearing

Digitized by Google

rver's mind the morning of July 10, n the bunched Glidden cars traveled n Cleveland to Toledo without being to see a car-length ahead.

is particular Gearless Model 60 was just finished on the day of the run and the first one of the new Schebler carators in use for the first time, which had no adjustment on the road and was n too saving of gasoline when we start- nd not quite liberal enough at any time, seemed to work extremely well.

e first thing noted by the observer was very smooth start and the silence of the motor and the transmission. The ne-gears are very quiet and the gearless mission is absolutely noiseless. The model of this gearless friction drive had -iron cone-rollers which made the big ng-cone and bigger driving-cup ring bells, but the fiber rollers are absolutely

. 10. The Gearless Transmission elements in ective, showing the cup, cone and cage of See caption of Fig. 3 in text.

less. The next point noted was the me readiness of speed-change, all ges made regardless of anything, and hird thing brought forcibly to the ob- r's attention came when the only acci- of the trip occurred. This was not so serious. The Tester's cap went adrift we were running about 30 miles, and Breyfogle, who is not a light-weight, perhaps wished to show the observer the Gearless transmission could do, ne of his feet against a pedal and made heels slide, and the next instant the r was hustling backward over the road trieve the blown-away head gear, all ence and more quickly than it seemed ble to stop and reverse the direction of of so heavy a car going at a good

erward, on pavement, with about a e rate, the reverse was put in when r was on high gear forward, with the of a perfectly smooth, quiet stop and quick start backward. One demon- on of the powers of the transmission was also made which nearly passed

headed our way, and gave us successive dus baths that made us regret our absent gog gles. The dust was deep enough to mak the car skid in many places as if on snow and the long road to Batavia, thru Cal donia and Le Roy is very crooked all th way and gullied, stony and rough in man places, and full of little, steep hills, all mak ing it a slow, bad route.

We picked up one dust-cloud after another each one containing a big car, and all bu one or two of these were cars that claim place in the front row, and none of ther waited for us to pass. We went by all bu one of them, which was traveling at abou our clip and raised such a dust that we with our unprotected eyes, did not care t chase it too closely, tho we passed it a soon as we struck Batavia pavement, havin done the 41 miles in 106 minutes tota elapsed time, which was very good indeed considering the rough roads, the new car the new carburetor and the dust-skid, which made the car try to stand crosswise of th road when any attempt was made to push i where the dust was deep.

The return was over a much better road some miles shorter, and with no cars i front of us. The carburetor did not giv quite enough fuel for best pace, and ou high rate was not more than 45 or 48 miles and that for only one or two short spurts as this road is crooked all the way and Mr Breyfogle is far from being a reckless driver We reached the Gearless Factory after a slow run thru police traps and the streets of Rochester, our total elapsed time for th 38 miles being 101 minutes. The fuel burn- ed was almost exactly 6 gallons for the 79 miles, which is a very good showing for a new car and 5 passengers, one of whom weighed 200 and the driver 225 pounds, so the car had a good 5-passenger load.

The clutch was tightened at Batavia, and this adjustment and that of the carburetor were all the new car had. This run was made on a Gearless 4-cylinder model 60 instead of on a Gearless Six, because there was no 6-cylinder car available. The Gearless cars are all shipt as soon as may be; this 4-cylinder car was ordered to be run all night so as to ship it at noon next day.

Mr. Breyfogle said the 4-cylinder could do about all the 6-cylinder could do, save to accelerate on long hills. We found plenty of hills between Rochester and Batavia, some of them very steep, but all short and these were rushed by the Gearless model 60 without much retardation.

or $4500, either as a runabout or tour-
r, and $5750 if fitted with a Limousine

THE SIX-TEEN-SIX MOTOR.

six-cylinder motor is composed of

detachable steel plates, as shown in Fig. 2, o
the right side of the motor. The aluminun
crank case has large hand hole inspectio
openings and is split into right and lef
halves which makes it possible to easil
remove the crank shaft cam-rods and piston
without disturbing the cylinders or connec
tions. This is a decided step toward th
very desirable quality accessability. Th
main bearings are clamped to the stationar
side of the crank case and are therefor
not disturbed. The inlet and exhaust mani
folds are held in position by yokes detach
able by a single nut each. All the working
parts are completely enclosed in dust an

oil tight housings. The fan is gear driven, but with a friction clutch connection interposed between it and the last gear to allow for sudden starting of the engine. All these gears as well as those used to drive the magneto are enclosed. This Eisemann high-tension magneto is mounted on an integral crank case bracket on the right of the motor and driven by a shaft with flexible connection from the gear combination at the forward end. These gears are of hardened steel meshing, either with brass or white fibre according to the duty required of them. An auxiliary ignition system is supplied consisting of single non-vibrating coil and an accumulator. The magneto carries its own distributor.

LUBRICATION.

The positive lubrication of all the motor

Headquarters for Automobile Chains and Woodruff Patent Machine Keys.

Digitized by Google

bearings and running in oil, flexibly but powerfully connects the engine to the change gear. The discs are forcibly engaged by a ring of six springs which distribute the pressure equally over their surface, giving much more uniform distribution than when only one central spring is used. The clutch is accessible for adjusting and is operated by a foot pedal independent of the brakes. A three speed and reverse selective type change speed gear is used, giving direct drive on the high, with a gear reduction of 2.64 to 1. The change gears are mounted on ball-bearings and an enclosed interlocking mechanism is provided.

The drive is by a cardan shaft practically horizontal and fitted with roller type universal couplings. An improved flexible coupling is also used between the engine and change speed gear. The entire driving mechanism is housed and securely protected from mud and dirt, no mud exposed chains or chains of any kind in fact, being found in the well-protected mechanism of the Winton. A steel dust pan extends from the forward end of the motor to the rear of the change speed gear case and an apron extends from the radiator to the pan, thus the entire under side of the car is thoroly protected. The mud guards are of prest steel of original design, webbed to the frame so as to completely protect the body from road wheel splash. The space between the running board and the frame is also fitted with a shield extending from the pan to the rear guard.

AXLES AND SPRINGS.

The rear axle is of the floating type, carries no load and is stayed by ball jointed torsion and radius rods of improved design. The axle shaft, differential gear and pinion shaft can be removed with the car standing on its own wheels, not even a jack being necessary. Timken roller bearings are used. The front axle is a one-piece I beam section Parsons manganese bronze casting. The well-known patented Winton twin springs are retained by a single clip which passes thru the center of the axle bed. The front end of the front and the rear end of the rear springs are banded to protect them against breakage by rebound. The front springs have 9 leaves and are 1¾ by 39¼ inches. The rear springs are 2 inches wide, have 11 leaves and are 52 inches long. Both are of the usual semi-eliptic form.

The frame is of prest steel, the sills or side members and the drop cross members being made of one piece, channel section. The intersections are strongly reinforced by gusset plates. The drop part of the frame carries the motor, clutch and change speed gear. The dash is of mahogany with a steel hood and carries nothing but the small auxiliary gasoline tank and the coil. The engine bonnet is of aluminum held by spring plungers.

Fig. 4. Chassis of the Winton Six-Teen-Six. Motor six cylinders, 4½x5 inches. Prest steel frame of channel section, with sills and cross members of one piece, no sub frame. Winton patented twin springs, three-speed and reverse, selective type change speed gear. Double set of equalizing brakes on rear wheels. Mechanism pan protected and all moving parts inclosed. No belts or chains are used anywhere in the construction, even the fan being gear-driven. Wheel 36 inches, wheel base 120 inches. Multiple disc, ball bearing clutch. Gasoline tank at rear with auxiliary gravity feed tank on the dash.

STEERING AND CONTROL.

The steering gear is of the screw and nut type with ball thrust bearings and the connecting linkage joints are fitted with heavy bushed bolts, no taper pins being used in the construction. These bolts are locked by cotter pins.

The steering knuckles are mounted on roller bearings. The usual spark and throttle levers are on top of the steering wheel but are friction retained in any position by the use of taper plugs spring prest into a V groove in the stationary sector. The outside hand lever controls the internal expanding brake and also releases the clutch. The inside hand lever controls the change speed gear. Two push pedals and an accelerator button are provided, the left pedal operating the clutch and the other the external brakes and is independent of the clutch. Both brake levers and brake pedals can be locked in any position. The brakes are operated thru equalizers and will hold equally well in either direction.

THE RUSHMORE FACTORY

will be more than doubled in capacity by the new buildings now approaching completion.

For nearly a year we have run night and day in the endeavor to keep up with our orders. For the season of 1908 we shall be able to make

Prompt Deliveries

on all sizes of the famous Rushmore Searchlights, Headlights, and Generators.

The new buildings adjoin the old factory, and are constructed of reinforced concrete throughout. The equipment will be the most modern of any plant of the kind in the world. The separate power house shown in the foreground will contain a 200 h. p. Koerting producer gas engine, and one of 75 h. p. for reserve use. Producer gas will be used for all annealing, brazing and soldering, and the buildings will be warmed by the waste heat from the engines. A separate brass foundry (not shown) will have a capacity of 15,000 lbs. of castings per day, and will deliver work to a number of outside concerns. An industrial railway will connect all departments of the new and old factory. All parts of our product will be manufactured in our own plant, and we shall purchase only the raw materials. With a capacity of 40,000 lights for 1908, we shall be able to handle the entire demand for the finest class of goods.

"THE SCIENTIFIC CARBURETOR"

EAST NEW MARKET, MARYLAND.

AUGUST 15, 1907

PUB. OF THE CYCLE & AUTOMOBILE TRADE JOURNAL,
PHILADELPHIA, PA.

DEAR SIRS:—

In reply to yours of the 5th inst. asking our reason for not beginning our publicity campaign in your August issue, as it was our intention at first to do, will state that it was because of the fact that we were afraid that we would be unable to make deliveries of our carburetor in such quantities as the introduction of an instrument, accomplishing the results that it does, would create a demand for, by the time that the August issue was in the hands of your readers; but as with this writing, Mr. Stevens' book, "Carburation," intended for free distribution, is in the hands of the printers, and the attempt to manufacture these carburetors in large quantities has advanced to a degree where some promise of being able to deliver with certainty in the near future is assured, we ask that you simply reproduce a fac-simile of this letter in the September number of the Journal.

As regards advance information of the device which we are about to offer to the trade, we hereby submit the following few words of explanation: We wish to explain that this company was formed for two express reasons: First, for the purpose of giving adequate financial protection to Mr. Stevens' patents covering an invention producing the remarkable results which it does in the gasoline engine field; and second: to assure its production in such large quantities as its introduction must certainly create the demand for.

As to the carburetor itself: However wonderful the statement may sound, it is nevertheless perfectly true, that in the practical testing of this device, we have found THAT WITHOUT ANY ADDITIONAL CHANGE TO THE ENGINE OTHER THAN THE ATTACHING OF OUR CARBURETOR WE ARE ABLE TO SECURE FROM 30% TO 50% (AND IN SOME TWO CYCLE ENGINES EVEN 75%) INCREASE OF POWER over that obtainable when using either the ordinary float feed, jet vaporizing carburetor having the auxiliary air inlet, or the later developed, float feed supplied system employing the Venturi tube method of vaporization, which types have been considered, up to the present time, the most perfect devices known for carburation.

As to the mechanism and operation of our carburetor will say: As is well known, the three essential constituents that go to make up a gas having the highest degree of explosive power are hydro-carbon, air and heat; in our carburetor these three elements are accurately measured (which measurements vary proportionally with the degrees of throttle opening). Next, these three components are thoroughly intermingled by contact with the vanes of a fan wheel revolving many times as fast as the initial velocity of the mixture, which fan wheel is actuated by its direct connection with a turbine wheel introduced into the path of flow of the exhaust gases. The combination of these two elements in operation produces the following results: First, the production of a gas (not vapor) always of absolute homogenity and correct proportions, which insures the highest initial explosive pressure upon ignition. Second, the assurance of a much fuller charge as the gases are forced into the cylinder under pressure from contact with the vanes of the fan wheel revolving at a high velocity. Third, the high momentum of the turbine wheel, having an average gas propelling velocity nearly equal to that of the exhaust gases when the exhaust valve is first opened, upon the decrease of the first exhaust pressure produces a vacuum in the exhaust pipe, resulting in a much more thorough scavenging of the cylinder, which leaves only a small amount of burned gases to mix with the fresh charge, which result alone, it has been shown by actual test to be capable of increasing the explosive pressure of the charge, upon ignition, from 15% to 25%.

A combination of the above mentioned operations, besides giving the already mentioned increase of power also produces the following results: 30% cooler engine, an entire absence of carbon deposit in the cylinder, an odorless exhaust, an actual saving of 25% in gasoline and 20% in lubricating oil, a much greater amount of flexibility, reliability and speed, a wonderful decrease in ignition troubles, and an entire absence of the need of regrinding valves.

With this much information borrowed from Mr. Stevens' "Carburation" and with apologies to its author,

We remain yours, for a bigger future for the internal combustion engine,

WAS / CHS THE E. W. STEVENS CO. WM. A. SAKER, Vice Pres.

THE SCHWARZ WHEEL COMPANY

try roads. This is an important feature if country touring is intended.

CONTROL AND BRAKES.

In the control of the car the hand lever on the right side combines both low and high speeds and when this lever is pushed back it applies a brake on the rear axle, which is ratchet-retained and is released merely by pressing with the heel a small plunger rod which is situated in the floor directly under the driver.

The throttle and spark levers are situated upon the top of the steering wheel, where they are within reach of the thumb and fingers at all times without removing the hand from the steering wheel. The reverse speed is operated by the right foot pedal.

The left foot pedal disconnects the engine and applies a brake upon the rear axle that may be applied at any pressure the operator desires.

A very prominent feature is that a person may use either the left foot pedal, the right foot pedal, or the hand lever at the side of the car, or any two of these, or all three of them for braking, as they all act as a brake upon the car.

The body is handsomely upholstered, being one of the features the makers pride themselves upon as well as the hill climbing qualities of the car. It is claimed nothing but the best leather and curled hair are used. The wheels are 32-inch fitted with 3½-inch tires. The equipment consists of two gas lamps and generator, two side oil lamps and tail light and a long tube horn.

The Packard Factory—Detroit

HUGH DOLNAR.

The Packard Company produced a total of 1129 cars from Sept. 1st, 1906, to June 1st, 1907, all either touring cars, limousines or runabouts. No Packard commercial cars were supplied during the time specified; the Packard Company has not abandoned the commercial car idea, but has been constantly building experimental trucks and delivery wagons, tho no final type of this class of motor vehicle has yet been fully decided upon as standard.

Of the 1129 Packard 1907 cars, 125 had both touring and limousine bodies fitted to the one chassis, making a total of 1254 car bodies of all three styles placed on Packard cars sold during the year. In addition the Packard factory is now filling orders for 100 limousine and 12 landaulette bodies to go on Packard cars of the 1906-7 models which were fitted with touring bodies only; these additional bodies will be completed late this summer. The Packard year ends June 30th. The Packard car bodies are composite constructions, wooden frame and sheet aluminum seat backs and panels, etc., requiring a very large floor-space in construction.

The Packard factories are among the world's largest, but not nearly large enough for the work in hand, and are now being increased by a new front building, reinforced concrete, 501x60 feet, two stories high. Something more than half of the first floor of this new front building will be used for the factory offices and the remainder will house the experimental department. This new front building faces south. The second floor will be occupied by the Packard general offices, at the west end, over the factory offices and the remainder of this second floor will be occupied by the drawing room and physical and chemical laboratories. The old offices in the southwest part of the previously erected Packard factory buildings will be used for factory offices when the general offices are transferred to the new front building.

Besides this new front building, now under construction, the Packard Company has this year added a third story to last year's front and east side buildings, 957 feet total length and 60 feet wide, also a connecting building, 128x60, three floors, now almost ready for use, which will be occupied by body-making and upholstering, and second stories have been added to two of the transverse buildings, each 200x 50 ft. This added floor, 200x50 ft., on the west side will be used as the rough store room, and that on the east for a factory restaurant on the first floor and tool-maker's department on the 2nd floor.

A restaurant has been maintained for the past two years in the Packard factory, supplying about 300 meals per day. This restaurant was turned over rent-free to a keeper who supplied meals to workmen as a private business venture of his own. This same man will have the new and very much larger restaurant on the same terms; the first was far too small to accommodate the workmen.

The Packard Company owns a flat plot of 23½ acres, with the Boulevard running thru it East and West, and Concord street bounding it on the east side.

The shops were removed from Warren, Ohio, to Detroit, early in 1903, and the Detroit buildings have been in course of enlargement almost constantly ever since, and when the new front building is completed the Packard factory will have 435,000 feet of floor space.

The original buildings are all of brick, all newer buildings are reinforced concrete.

The Packard pay roll has carried as many as 1846 names, which number will be largely exceeded in 1907-8.

The General Vehicle Company, of Long Island City, N. Y., heretofore manufacturers of heavy commercial electric vehicles, will add a light pleasure car to their productions. The new car is scheduled to make its appearance on the market early in the fall.

1908 Motors of the Continental Engine Co.

The Continental Engine Co., 503 Fisher Building, Chicago, Ill., has recently brought out a new line of motors that have been designed along lines embodying foreign practice.

The engine is of the separate cast cylinder type, with five main bearings, and uses oil rings in the long end bearings. The diameter thruout of these and the crank bearings is 1¾ inches.

The exhaust valve was, after tests, placed centrally at the top of the cylinder in a removable cage for easy access and absolute seating. This method allows of direct exit for the exhaust, and enables the exhaust pipe to be placed on one side with the intake on the other, yet have but one set of cam gears. This system of long intake ports and short (entirely surrounded with water) exhaust, it is claimed, gives cooling facilities that enable motor car builders to reduce their cooling source at least 10 per cent. over the twin cylinder type, as can be proven by the company's tests.

The exhaust pipe is of the tapering type, increasing in volume to suit the continual expansion of the gases and fits a 3-inch muffler pipe connection. This system is claimed to produce silence without special muffler provision, and reduces back pressure in any portion of the pipe to two ounces per square inch.

The cam gears are made of bronze and cast iron cut herring-bone style, so as to insure absolute silence without using flexible material subject to excessive wear. These gears, as well as the pump drive gear and magneto drive, are all housed in an easily removable case in front of the motor. Pump is furnished either of the centrifugal or gear type to suit, direct driven from gear in front. Commutator shaft is vertical to above cylinders, and is driven by housed-in mitre gears. Provisions are made for magneto, direct driven by gear in front.

Accessibility to parts on this motor is one feature of the design and the large handhole plates on the side are removable by simply loosening the nut in the middle and turning spanner bar over same. The cam shaft is in clamped bearings removable from front in assembled condition by simply loosening a clamp bolt. The plunger rod guides are also easily removed. Fly wheels are made to suit any clutch or to fit the new multiple disc clutch of the company.

Sectional view of 1908 Continental motor, 45 H. P. at 850 revolutions. Bore 5 inches, stroke 5½ inches. Speed from 150 to 1600 revolutions. Complete weight 480 lbs. Height from center of shaft to top 23½ inches, and from center of shaft to bottom 5½ inches. Width between hangers 17 inches. Length over all, including flywheel, 38½ inches. Price, with standard equipment, $800.

STANDARD EQUIPMENT.

Metal spiral cam and pump gears in complete housing, water circulating pump built with and geared to engine, intake manifold, carburetor pipe, exhaust manifold, complete brass ball "T" joint water pipes and connections, commutator, spark plugs and clutched starting crank, with counter clutch for same on engine shaft; balance wheels furnished of different diameter to suit any clutch. Arrangement for magneto attachment and direct drive mounted as part of motor.

DOUBLE OPPOSED AIR-COOLED MOTORS.

The company has also just completed a line of air-cooled and light-powered motors in addition to their line of water-cooled motors.

The engine is four-cycle, with mechanical exhaust, automatic intake, self-contained cooling fan fly wheel, special white metal bearings thruout, and provided with absolutely automatic lubricating facilities, built

Helmet Oil

NEVER FAILS TO LUBRICATE

HELMET OIL is a hard oil. It is not a common liquid oil, but has "body" or density that *resembles* lubricating grease. Helmet Oil will give satisfaction on every bearing of your automobile.

Try it on the bearings that give you the most trouble and you will find that t will give perfect lubrication.

The crankshaft bearings and the gears generally give the most trouble because of the enormous pressure, which forces common liquid oil out at the sides or burns t up into a tar-like substance or residue. Some oil manufacturers do not even claim that their oil will effectively lubricate these parts.

Helmet Oil will not only lubricate crankshaft bearings and gears, but it will ubricate every other bearing on your automobile effectively.

The reason that Hemlet Oil gives such good service is on account of its "body" or density. It can't be forced out at shaft ends, and it is such a thorough ubricant that the bearings cannot become hot and bind. The bearings are always as clean and as bright as the metal itself. There is no black, tar-like residue.

Arguments and statements of facts are all right, but—***we will prove ours to you.***

A Trial Test Free

We will give you enough to try it on your car. Put it where you are having the most trouble.

Send us the name of your dealer and we will have him give you a quantity to test.

he type "B" is a double-opposed 10-horse ver motor at 850 R. P. M., so designed o meet the requirement of a motor suit- for cross or lengthwise hanging in a ssis or frame of any kind, and yet re- e but a comparatively narrow frame, as following specifications will readily w:

ore, 4 1-16 inches; stroke, 4 inches; th over all, 26½ inches; distance be- en hangers, 17 inches; weight (complete 5-spoke fan fly wheel), 130 pounds; cen- of cylinder to centre of hanger vertically, inches; diameter of fan fly wheel, 17 es outside; diameter of crank shaft bear- , 1 5-16 inches; length from outside to side of main bearings, 9½ inches; cranks 80 degrees and running in white metal rings.

SPECIAL FEATURES.

pposed cylinders on one casting. Ex- st directly down. Intake made inter- ngeable to the side or end. Removable e-seated cylinder heads avoiding gaskets. nk case and cylinders rigidly cast in one e. Large removable cover over top for ection of moving parts. Hanging, suit- for any frame, on 1-inch standard pipe, s also the exhaust pipe. Normal speed, revolutions per minute. Cam shafts on izontal line, with crank shaft to admit access to all parts from top by removal one plate without interference with cam ft. Intake tube of rolled brass, with matic intake valves inside of pipe to d all leakage and yet made for easy ection by simply loosening one nut. Steel am section, adjustable connecting rods special non-heating bearings. Hollow lened steel piston pins. Double spark system and easily removable exhaust e.

he balance of all moving parts, they be- inclosed and supplied by oil direct from k case, the exhaust and intake piping bined to one outlet in each case and the ging being suitable for any frame, with cooling provision embodied within the vheel, and the extreme over-all length of 26½ inches makes this a most de- ble and specially-adapted outfit for motor cles and portable work. The heads of cylinders are so made as to prevent heating, contain one provision for a k plug, are screwed into a bevel seat to in absolute tightness without depending the thread for the same and without ets of any kind.

he cam gears are placed horizontally in with the crank shaft inside the case, cylinder. This makes a definite constru tion, and is an oil and dust-tight compar ment for the cam, which can be filled wi hard oil so as to insure protection from u necessary wear.

The exhaust valve stems have lo guides and are directly in line with t plunger rods, so that no irregular or twi wear is presented to the action. The guides are integral with the main castin as is also the valve seat, the throat of whi is 1½ inches diameter, with plenty of g clearance around the seat in the valve char ber. This valve chamber is also cast integr with the main casting and has two outle for the insertion of the intake, one endwa in line with the exhaust valve and the oth at right angles, going horizontally to the sid and both being made to either receive t intake pipe or an inspection nut. These a interchangeable, so that the intake can b placed at right angles to the motor or tak from the end. The side, or right angle, p sition is, however, strongly advised, so th

1908 Type N, 10 H. P. air-cooled Continent Motor, fitted with flywheel fan. Bore 4 1-16 or inches, stroke 4 inches. Length over all 26 inches, distance between hangers 18 inche Weight complete with flywheel 140 lbs. Price $1 The intake can be placed at the side or end. T heads are valve seated without gaskets, and t cylinders and crank case are cast integral.

the blind nut can be placed at the e thru which the exhaust valve could removed and inspected without disturbi the intake piping, which contains the in valve and valve housing in such a mann as to make the whole retained by a hex n screwed into the cylinder casting. This co struction admits quick and easy access wi an absolute air-tight arrangement so nece sary for automatic valves. This compan after thoroly trying out, as stated abov both automatic and mechanically-operated i takes, definitely decided on the latter f water-cooled engines and the former for ai cooled products.

ɔe "N" is out of the question. Bearings d internal construction are similar to the ɔe "N," and the shaft bearings are 1¼ ches diameter thruout.

New "Rands" Runabout Top

Rands Mfg. Co., 51-55 Macomb street, etroit, Mich., has just added to its line tops a new style for high-powered run-outs. The new top is very practicable for s type of car and has won favor in the inity of Detroit.

There is no bow extending from the side the seat to the front part of the top and erefore, no obstruction in the way when e is mounting the seat. The top is long ough to extend over the dash and when ed with a wind shield gives ample pro-tion in inclement weather. Two side cur-ns can be attached to the edge of the front at with fasteners which can be left there rmanently if desired.

New "Rands" Top for High-Powered Runabouts.

On some cars this top can be folded back thout interfering with the occupant of the ar seat. It is raised or folded by means two thumb screws, being detached from e upper part of the center socket and ced at bottom of same socket.

1908 "Vivax" Sparking Battery

Vivax Storage Battery Co., 2228 Michi-n avenue, Chicago, have made some im-ovements in their storage ignition battery 1908, and herewith we give a detailed de-ription of the new model of this battery, ich has been but briefly mentioned in ese columns.

The elements are in rubber cells and the lls are enclosed in an oak case made of -inch material, dovetailed. The bottom grooved in all around, so that it cannot op out. Corners are rounded. The case

The 1908 "Vivax" Sparking Battery.

their own grids and plates. The active m terial is so lockt in that no particles c become detached and fall to the botto but to doubly guard against this contingen a half-inch space is left between the bott of the plate and the bottom of the jar. P forated, hard rubber separators are used tween the plates.

After the cells are placed in the ca the space between them and the inside of case, about ⅛-inch all around, is filled w a composition which holds the battery one solid mass and which does not m from heat or crack from cold.

The covers which go over each of compartments fit tightly around the term als and over these covers is flowed ab ¼-inch of composition, which prevents acid from creeping from the poles. Insu ing wire which is imbedded in the compo tion, prevents creeping of any acid fr the poles to the terminals.

The capital stock of the Hartford A Parts Company, Hartford, Conn., has been increased from $10,000 to $35,000.

The Springfield Motometer

Now offers, covered by the same guarantee and backed by the same record of proven goodness as for the two seasons past,

These New and Valuable Features:

A Maximum Hand which is Perfection.

Travels up the scale with the regular pointer but remains at the highest speed reached until released by the pressure of a button when it instantly drops to the point where the regular pointer may be standing at the moment. It can be made inoperative in an instant, traveling with the regular pointer up and down and being invisible.

The Handsomest and Most Readable Dial Made.

Large, Symmetrical Figures in jet-black fired enamel, on a perfectly white enamel ground. Read with ease from the back seat of any tonneau. It will please all critics of the old one.

New Oil Tempered Spring Steel Reinforce,

at each end of the shaft. Prevents a short bend. Compels the easy curves necessary to smooth running and long life, which no make-shift in the way of gears can replace.

The Non-Clogging Pinion.

Will not hold mud. A straight-forward and correct mechanical device of absolute efficiency.

These are additions, not changes. With them the Motometer is even more than before "The Speedometer For Service."

50-Mile Model, $45.00. **60-Mile Model, $50.00**

Either with Maximum Hand, $5.00 Extra.

¶ The one vital point of a searchlight, and the point that determines its light value, is not the amount of metal, or the size of the flame, but the refraction of the light rays. And that is what our Mangin Lens Mirror does—it condenses the light pencils and utilizes the light that is otherwise scattered.

CAREFULLY conducted experiments prove that a searchlight fitted with the

Bausch & Lomb Searchlight Mirror

will give 50 per cent more light than with the ordinary reflector. The reason is that with our Mangin Lens Mirrors the greatest possible number of the light rays is used—they are reflected and refracted into a solid beam of light, so that instead of the light rays being wasted they are all concentrated within the area required to light the roadway.

¶ It is *used* energy that counts, *used* light that illuminates.

¶ The genuine Bausch & Lomb Mangin Lens Mirror bears the mark "B. & L." on its face. Insist upon having a lamp fitted with our mirror.

¶ "PRISM" IS A LITTLE MAGAZINE we publish monthly. Not a mere advertisement, but a beautifully made and printed little publication about that world of wonder and beauty seen by the lens. Send us your name and we will enter your subscription FREE.

furnish a reliable spark on a minimum rrent consumption. This is accomplished t only by the correct proportions of the mary and secondary coils and conden-s, but by the use of a balanced vibrator, exclusive feature of this coil, which is ly protected by patents. The armature is unterbalanced in such a manner that the

New "Mesco" Jump Spark Coil.

aking and jarring of an automobile can-t interfere with the uniform movement of vibrator. This permits of the vibrator ng set at a very light tension, and as the nature is of light weight it responds in-ntly when contact is made at the timer, d there is no loss of current or time in rting the vibrator and securing the spark. Adjustment (which can be made while nning) is by one screw only, which turns ely but is held against accidental move-nt by a locking spring.

The best iridium-platinum is used for the ntact points. The parts carrying these nts can be readily replaced by anyone en renewals are required, but there is so le sparking at the points that they last ch longer than is usual.

The dashboard type is made for one to cylinder machines, with removable units ich automatically make contact when slipt o place. Both dashboard and marine es are very small and compact. The kers claim that a sufficient spark for iting any gas engine is obtained by a cur-t consumption not exceeding three-ths of an ampere.

Columbia Machine & Malleable Iron Co.,

ufactured without the use of bark. It produced by a secret process said to re in a much superior leather at a much sm er cost and in less time than bark-cu leather.

Antioak tires are made of two and th thicknesses of Antioak leather with an a friction coating between the layers. Th tires are said to have been tested at a sp of 60 miles per hour without overheati As these tires are unpuncturable and c not blow out or rim-cut, they appear to a promising proposition, especially as makers claim great resiliency for th They are also impervious to oil, water, li or heat and cannot lose their shape as stretch is taken out of the leather. A st lug tread is another feature of Antioak ti

"Wabash" Automobile Parts

The Wabash Auto Gear Works, Terre Haute, Ind., have recently placed on the market a line of automobile parts, some of which are herewith described and illustrated.

Their selective type transmission gear is made in two sizes, one of 20 to 40 H. P. capacity and one of 40 to 80 H. P. The sectional view of the transmission gears shows a hollow axle which is larger than usual and is fitted with 4 keys milled solid on the shaft. This shaft is made out of Special 40 Pt. Axle Steel and the primary

The "Wabash" Transmission Gear No. 1. 20 to 40-H. P. Selective Type.

axle, made of the same material extends almost clear thru the transmission proper, and runs in fine special bronze bearings. A notable point in this gear is its lubrication which is accomplished by inserting a felt sleeve around the primary axle between the two bronze bearings and filling the cavity at the inner end of the primary axle with felt so as to have the primary axle run against oil soaked felt all the time, thereby insuring perfect lubrication. The gears are all of large diameter and are secured to the shafts by long hubs and heavy keys. The small countershaft gear is made a part of the low speed gear, and therefore cannot slip, while the long hubs to the countershaft gears keep them from slipping, or getting out of true.

The countershaft is placed under the hollow axle so the gear will lay down in the car out of the way, which allows the reverse gear to always run in oil. The case will bear filling to the top, and is provided with packing glands to prevent leaking.

While roller bearings are shown, the same gear case can have annular or bronze bearings, as it is made to interchange perfectly. The pull rods are adapted to be easily fastened to the Wabash control set, which are of the selective detachable lever type.

In the cut of the Wabash control lever set, the device is seen to be a complete unit, as the emergency brake lever is carried by the same bracket which bolts onto the frame so as to allow placing it to the best advantage. The angle of the levers can be set to suit the car, as the frame of the bracket is adjustable, as shown, and can be pinned or riveted when set properly.

Both levers are made from the same forging, and have the regular grip handle. This grip controls a little key on the selective lever and causes it to pass up or down from sub lever B into sub lever C, etc. The spring at the top of the control lever handle holds the key at the top position which keeps the key engaged with the sub lever C, which sub lever is brazed to tube C, and if this tube is connected to the pull rod con-

The "Wabash" Selective Type Control Levers.

trolling the low and reverse speed and the sub lever B connected to the pull rod controlling the middle and direct speed, then the action will be levers in normal position push forward to get low gear and pull clear back to get reverse, and come to neutral position and press the handle grip which will send the selective key down into the top of sub lever B then we have direct speed forward and middle clear back, or the levers may be connected so as to give the high and middle gear in the normal or top position, and low and reverse in the bottom position. They also make a cone clutch which fits the majority of automobile engines that are using cone clutches. The cone clutch is furnished with control rollers and bolts for them to run on, and proper nuts for fastening. The clutch is provided with a leather face which covers the whole face of the cone. The connection for the coupling to the transmission is furnished with each clutch complete for installation.

The John Obenberger Co., 220-224 Lake street, Milwaukee, Wis., manufacture a general line of hammered forgings, crank-shafts up to 1000 pounds, and all kinds of gear blanks and special forgings. They also do rough machine work or finish complete.

Universal Type Engine

The One Best Engine For Buggy-Type Automobiles

Suitable for any light runabout or light delivery wagons, but designed especially for buggy-type rigs.

Two cylinders, 4x4 double opposed.

Conservative power rating, 10-12 H. P.

Weight, including flywheel, 180 lbs.

Over all dimensions, including spark plugs: length, 30″; wihth, 16¾″; depth, 17″. Depth without flywheel, 11½″.

Perfectly balanced. Entirely free from vibration.

Air-cooled, and **cooled** beyond question. Has been run at full speed for six hours without a sign of distress. Big exhaust valves. Careful construction. Best materials.

Every engine fully guaranteed to deliver the rated power and keep cool.

Prompt delivery on any quantity to those who order promptly. Attractive prices in quantities.

pers, have recently placed on the market sheet metal step hanger shown herewith.

he "Crosby" Stamped Sheet Metal Step Hanger.

he special advantage of this method of ufacture are lightness, cheapness, and ngth. The manufacturers are prepared urnish these hangers in any number.

The Helix Flexible Shaft

he Helix Mfg. Co., of Stapleton, Staten nd, have brought out a new flexible wire for fan and lubricator drive. This belt a new form of connection (patent ap- l for) which is extremely simple, and claimed does away with the breakage at joint. The belt is made of one piece of o wire, joint included, and is connected he use of the hands only, no tools being ired and the attachment or detachment ng less than a minute to effect.

he Helix wire shaft is made of 16 nds of high tensile strength German o wire, wound in four layers of four nds each, each layer alternating in di- ion of winding with the superposed r. The effect of the process of winding l only by this company is to produce a ible shaft which, it is claimed, is without buckle common to the ordinary wire t, and gives extreme resistance to torque ied at the end because of the disposi- of each strand to act as a tension or pression member in resisting the load. load put on this shaft is distributed ormly thruout the whole and does not e upon the ends nor does it come upon surface layer, and the shaft will work lly well running right or left hand.

his shaft was developed by Mr. H. W. ob from a scientific study of the defects the wire shafts formerly in use. Find- that these shafts would break under a l which was far smaller than the known ngth of the wire units composing the ft, he sought a proper method of distrib- adaptation of design.

They have given this belt a long and se vere test before placing it on the marke and claim to have found that the joint equally as strong as the rest of the belt. Th connection is practically invisible, and as is of the same diameter and of equal flex ibility thruout, the drive is noiseless. Th belt can be adjusted for length or for stretc thru long use by the simple process of cuttin off a length from one end. The highe grade piano wire obtainable is used, the se vice requiring a high elastic limit. They a in all sizes from ¼-inch to ⅜ diameter. special introductory price of $1.50 for fan c lubricator belt has been made, and the guarantee satisfaction or refund the mone

The company make all sizes of flexib shafts for speedometers, odometers and s rens, and claim the Helix shaft has bee adopted by nearly all the principal speedo meter makers, and is rapidly becoming th standard shaft for this work. They als state that it is the only wire shaft that giv dead beat reading in a speedometer.

The "Vaugier" Automobile Crank Handle Protector

The accompanying cut shows the Vangi crank handle protector, recently placed c the market by the Vangier Specialty Mf Co., Piqua, Ohio.

With the use of this device the cra can be drawn up from the perpendicular any desired angle, and as the protector gri the handle firmly it eliminates all rattle a also keeps the handle free from mud a

The "Vaugier" Automobile Crank Handle Protecto

dirt. Another advantage is that with use all danger of losing the crank is obv ated.

The protector is made of polished bra in two sizes; the smaller for handles fro ½ inch to 1⅜ inch in diameter and t larger size for handles up to 1⅝ inch. double compound spring contained inside t protector makes it self adjusting to any si handle within the sizes mentioned.

SPLITDORF
TRADE MARK
N·Y·
LABORATORY

What Does This Trade-Mark Mean?

It means that into every piece of Ignition Apparatus turned out by SPLITDORF is put as much skill, as much pains, as much fine material, as if that one piece were the only one to be produced—the only one by which the reputation of SPLITDORF were to be judged.

It means ABILITY gained by the LONGEST EXPERIENCE of any coil maker in America to make the **Most Efficient, Most Reliable, Most Economical** Ignition Apparatus on the market.

This is why every SPLITDORF COIL is up to the same high standard. This is why "Splitdorf" always means the same—judged by the one sterling quality—merit.

It is just as easy and costs no more to have the best.

Trade Printed Matter

The most elegant and pretentious piece of automobile advertising literature extant is the latest catalog issued by Packard Motor Car Company, of Detroit, Mich. This handsome production is the result of the combined efforts of E. Ralph Estep, designer and writer, several prominent illustrators, the Peninsular Engraving Co., and the Matthews-Northrup Co., printers. They have reason to be proud of their work for the publication they have produced is too handsome and effective to be described and it sets a pace in the automobile advertising world not likely to be exceeded. It is enveloped by a folder covered with illustrations of the Packard radiator and enclosed in a neat cardboard box containing in gold the name of the recipient. The decorative scheme includes two highly illumined pages in antique style and is thruout attractive and appealing to good taste. The reading matter is forceful and impresses the reader with the carefulness and thoroness with which every operation in the production of "Packard Thirties" is performed—from the designer's conception of his ideal to the final and very thoro test given to each new model before it is sold to users.

A very neat and elegant little catalog was recently issued by the Pope-Waverly factory at Indianapolis, Ind., advertising their electric Phaeton and showing its especial adaptability to varied uses; for women, for example, as a lady's runabout, Victoria phaeton, park phaeton, open Victoria and with folding buggy top. This catalog is gotten up in tasteful form, which will appeal strongly to the refined instinct of the gentlewoman to whom it is addrest.

Breeze Carburetor Co., Newark, N. J., have taken advantage of the fact that the Christie Grand Prix racer is fitted with their carburetor by issuing a folder containing a picture of the racer illustrations of the Breeze carburetor and Breeze gasoline strainer and several strong testimonial letters.

A small, but comprehensive, instruction book has lately beeen issued by Witherbee Igniter Co., 541 W. 43rd St., New York, for the benefit of Witherbee storage ignition batteries. It contains in its 16 pages all the information necessary to obtain the best results from these well-known batteries and explains fullly and clearly the operations of charging, etc.

Cadillac Motor Car Co., Detroit, Mich., have issued a set of 8 photographs all on one large sheet, illlustrating a Cadillac car carrying mail in Hawaii.

C. Cowles & Co., New Haven, Conn., have lately isssued what is doubtless the largest and most comprehensive catalog of automobile hardware and top fitting that has yet appeared. It contains 170 large-sized pages and is printed on a fine coated paper on which the many illustrations show up to excellent advantage. Several fine limousine fittings are shown in addition to a very extensive line of usual top irons, screws, bolts, strap buckles, and other commmon fittings.

The advantages of using "Prest-O-Lite" gas tanks are very convincingly and clearly set forth in a neat brochure recently sent out by the manufacturers, the Prest-O-Lite Co., Indianapolis, Ind. A number of very effective illustrations are used, chief among which is one of a limousine car lighted entirely exteriorly and interiorly from a "Prest-O-Lite" gas tank.

The Gasket Supply Co., 1516 Sansom St., Philadelphia, Pa., have issued a new catalog of gaskets, which covers every requirement in this line, and will prove of value to any mechanical man having steam, water, air, etc., joints to pack, for between its covers he surely will find illustrated and described a gasket that will meet with his requirements. It is a very pretty book, printed in two colors and enclosed in a beautiful embossed cover, which does credit to both printer and designer.

On account of frequent requests for suggestions, plans and specifications received by S. F. Bowser & Co., South Bend, Ind., that company has recently issued a book entitled "Plan Drawings of Model Oil Storage Systems," which they are placing in the hands of those interested. This book contains a full set of plans to meet every phase of the oil storage question, giving sizes of oil tanks, dimensions of oil houses, proposed layouts for public and private garages and all other necessary information for the equipment of garages, factories and stores with oil handling devices. The plans have all been compiled from actual installations.

The instruction book of the Correspondence School of Motor Car Practice, the issue of which was delayed by a disastrous fire in the printing plant, has at last made its appearance and is a 175-page book containing a large amount of rudimentary and technical knowledge regarding the construction, care and operation of motor cars. This course of instruction is the work of the Maxwell-Briscoe Motor Co., of Tarrytown, N. Y., and is furnished to Maxwell owners at cost while to others a slightly higher charge is made.

The Auto Top & Trimming Co., of Pontiac, Mich., manufacture a complete line of automobile bodies, tops, trimmings, etc.

Auto Accessories Sales Co.

The Auto Accessories Sales Co., 227 Victoria Building, St. Louis, Mo., has recently been organized for the purpose of representing the manufacturers of high-grade automobile specialties, and consists of Mr. A. Hollaender and Mr. Geo. W. Edge. Both of these gentlemen have been connected with the automobile business for the past six years.

They are western and southwestern representatives for the "Springfield Motometer," "Fleur de Lis" Dry Cells, "American" Ignition Apparatus," "P. D." Storage Battery Rechanging Panels, "P. D. Connectors," Standard Lamps, and Eldredge Electrical Instruments.

They now have a man in the extreme west and one in the southwest, in the interest of the manufacturers whom they now represent, or for any others who desire representation in those districts.

"Blue Ribbon" Varnishes

Beckwith-Chandler Varnish Co., 320 Fifth avenue, New York City, devote their entire efforts to the production of high-grade varnishes and make a specialty of varnishes for automobile finishing. Their line of motor car varnishes is called the "Blue Ribbon" series, and includes "wearing body" varnish for finishing coats on the best work; "medium wearing body" similar to "wearing body" but a quicker hardener; "durable coach," a heavy body finishing varnish which hardens more quickly than the two afore mentioned; "durable gear" and "quick gear," for running gears; "elastic rubbing"; "quick leveling," "quick rubbing," "black enamel," for iron parts; rough stuff for either wood or metal bodies and "wood priming."

They claim that these varnishes flow perfectly, are easy to work and absolutely uniform. They possess the characteristic of extreme paleness and produce a very brilliant and durable finish.

The Calhoun-Bancroft Co., 506 Third avenue, Seattle, Washington, representatives of automobile and launch accessories, are offering Eastern manufacturers an exceptional opportunity to place their goods before the trade in Washington, Oregon and British Columbia. They are in the market for any good lines not conflicting with those they already have. The following are among the firms already represented by them: Connecticut Telephone and Electric Co., Vesta Accumulator Co., Progressive Mfg. Co., and the Hercules Auto Specialty Mfg. Co. Mr. Calhoun is an expert electrician and battery man, and Mr. Bancroft has had a broad experience in general supplies, having formerly been with the Motor Car Supply Co., and the Franco-American Auto and Supply Co., both of Chicago.

Dealers' Department

The Problem of the Grafting Chauffeur

Brewer, Maine.

The practice of paying commissions to chauffeurs on account of sales of tires, accessories, fuels and repairs is indeed a fit subject for discussion at this time.

This abominable condition was brought about in the early days thru keen competition and business rivalry among the dealers and repairmen and the then small sowing of thistles, has taken such firm root and spread so rapidly, that they now over-awe all who would attempt to stem the tide of their progress.

Thruout the breadth of this fair land this system of graft has sped from the great cities, contaminating the local chauffeurs, dealers, garage and repairmen until all are heartily sick of it except the grafters.

Most small dealers and repairmen are afraid to make a decided stand for fear of losing their trade to some rival in business and so they submit without protest. Not only do the grafters boldly claim their commission, but worse yet, they seek to, and in many cases make the garage and repairman their instrument in assisting to rob their employers.

For instance, a driver brings his employer's car to my place for certain repairs and replenishments, etc., "How much gasolene did you furnish?" Eight gallons, I reply. "Make a bill for ten." How many hours' labor, etc.? Three hours at sixty cents per hour. "Well, make the bill read four hours." Then he counts you out the price of the actual repairs or jots down in his graft book the amount of the "Commission" due him, when his employer settles the bill.

I read in some trade paper last Spring that several leading garage men in New York, with a view to stopping the abuse, had decided to notify owners of the grafting propensities of their chauffeurs. Did they do so, and what were the results? I doubt much if any such action was ever taken, but think the plan a good one if a firm stand by all in the business could be brought about and an open avowal and agreement made to absolutely refuse to do business thru such chauffeurs, and then adhered to until the graft situation was absolutely stamped out.

If a few in the large business centers would take some such action it would doubtless be followed by local organizations in the smaller cities and towns and in time the nuisance would be largely abated.

A thoro canvassing of the subject and much publicitiy are very desirable as they serve to intimidate the enemy and make the attainment of victory, less strenuous.

In going over this whole question with a brother repairman recently, I put the question: Well, what is the remedy? He took time to think deeply then brightened up as though he had solved the problem and said: "Forget it," and unfortunately this seems at the present time to be the general attitude toward this shameful situation.

THE BREWER BICYCLE & AUTOMOBILE CO.

Geisel Automobile Co.'s New Garage

Geisel Automobile Co., Springfield, Mass., has just had completed a new garage which is constructed with a trussed roof so that there is not a post in the building, a feature of especial and obvious value in an automobile garage. The dimensions of the building are 52 x 126 feet. Windows are on the east side, and run the entire length of the building, extending clear to the roof and making the garage as bright as outdoors.

There is a front door 14 feet wide, and at the southeast corner there is another door 16 feet wide. A washstand is located in the northwest corner and is 18 x 24 feet. It is equipt with an overhead washer which can be swung around the largest cars.

On each side of the garage are seven drop lights with 25-foot cords, so placed as to be handy for any desired inspection.

This model garage is in the center of the city within one block of the railway station close to the best trade, and conveniently located for getting the transient trade. Already plans have been made for a 50 x 90 foot L addition to be used as a repair shop.

The large garage of the Keystone Motor Car Company at 216-18-20 North Broad street, Philadelphia, is now in course of construction. The garage will be of fire-proof construction thruout, and will cost $50,000.

Some timely hints on the care of tires comes from Mr. J. C. Matlack, of the International Tire Co. Many motorists are having difficulty this hot weather with the patches coming off the inner tubes. It is a mistake, says Mr. Matlack, to depend upon patching, particularly during this hot weather, as the heat of friction together with the heated condition of the atmosphere loosens up the patch. Motorists would save time and money, to say nothing of temper, if they would send their inner tubes to some reliable supply house and have them vulcanized. This insures a lasting repair.

Hosted by Google

Philadelphia Branch Winton Motor Carriage Company

One of the progressive agencies of the Quaker City is the old-established branch of the Winton Motor Carriage Co., at 246 North Broad street, Philadelphia. This has been a branch of the Cleveland plant since 1901 and has been since that date under the personal management of Mr. A. E. Maltby, one of the pioneers in the automobile business. A large and well-equipt garage and machine shop adjoin the spacious show room and offices.

Substantial business methods are responsible for the growth and permanency of this branch. All advertising is controlled by the main office in Cleveland, where a campaign for the season is laid out and rigidly adhered to. Allotments of advertising copy are sent to each branch for the newspapers and periodicals. No special window or street advertising is resorted to, and the statement was made that by far the largest part of the purchasers came not thru advertising, but by personal contact with Winton users. Daily paper advertising is simply depended upon to keep the name before the public. No regular system of follow-up letters is employed, the management believing that most of such matter receives very little attention and goes into the waste-basket, and that more actual progress can be made in five minutes conversation than in several letters. When a name is received one of the salesmen is detailed to see the prospective purchaser, talk Winton, get his interest aroused, take him for a demonstration and at any cost make a friend of him, whether a car is sold or not. Occasional visits are paid him until he either buys a Winton, some other car or signifies his intention of waiting until the following season, in which case his name and the state of affairs are recorded and filed either as a live prospect or to be held over a season.

Mailing literature to names on license lists, even when up to date, has been abandoned, owing to the fact that it is impossible to distinguish owners from chauffeurs. The management believe firmly in "casting bread upon the water" by making a friend of every prospective purchaser, and the number of sales made to persons who were at times enticed in other directions, but ultimately returned, is proof of the correctness of the principle. When a salesman after expatiating upon the good points of the car feels that the customer is yet in doubt he usually refers him to some owner, whose few words of recommendation are likely to carry the deciding weight.

Satisfied purchasers are the first consideration. All Winton owners receive the same attention, it being sufficient that they belong to the class of owners. If in trouble at any time a telegraph or telephone message will be instantly responded to, even if necessary to send a mechanic by railroad to the vicinity. If a recent purchaser lives at some distance, useful information which he would otherwise be unlikely to get is mailed to him, at the same time accompanied by a letter of inquiry as to his success with the car. If a repairman goes into his neighborhood he is instructed to drop in and look over the car and report. Every effort is made to keep all purchasers entirely satisfied, and thus live advertising mediums for the company.

The shows are believed to be very profitable, as they bring those most interested into direct contact with the salesmen, who thus secure a valuable list of prospective purchasers. Twenty-five sales are said to be directly traceable in this way to the Philadelphia show of last year.

BUSINESS SYSTEM.

In connection with the garage a daily floor card or printed form is used. Upon this a complete record of the going and coming of the car, the work done upon it

Digitized by Google

and also the supplies furnished is kept. The headings are as follows: Owner, Out, Taken by, Check by, In, Returned by, Check, Washing, Lamps, Gas, Check, Gear oil, Check, Cyl. oil, Check. From this it will be seen that not only are the amounts recorded, but the persons who put the work, oil or gasoline upon the car are known and also those who took the car in or out. From this form a weekly blank as illustrated in Fig. 1 is mailed to all owners who have chauffeurs in charge of their cars. The drivers object, but the system is very satisfactory to the owners.

In connection with the daily floor card a monthly record blank is use. The daily records are copied into this blank, a duplicate of which with its carbon impression is filed in a loose leaf binder and furnishes the totals for the day book, the original being mailed as an itemized bill direct to the owner. Records of all shop work are kept on a working order blank. On the front of this is the job number and statement of the necessary work. On the back is kept a record of the materials and parts used. Repairmen use a Perry time stamp on the job cards to record the exact time of starting and stopping on each job or ringing off or in on another job. Every piece of material taken from the stock room requires a requisition blank with the same number as the job and these requisitions are then filed by the foreman with the working order blank under the proper number, thus giving a complete record of the work done and by whom.

EVILS OF PAYING COMMISSION TO SALESMEN.

All the salesmen in this branch are on salary only, no commissions whatever being allowed, the management believing that many evils are due to the commission system. For example, a customer takes a fancy to a certain dash fixture and desires it as part of the equipment—the salesman on commission, thinking he may otherwise lose the sale, furnishes the required device out of his commission. The next customer probably asks something more than the former one and perhaps gets it from another salesman, etc. If such promises of accessories and parts happen to be made by a salesman who leaves the company's employ before the sale is consummated, trouble will surely follow, as the firm naturally refuse to cut prices in this way, as that is what it really amounts to, and the customer is disgruntled because he has heard of others who did get certain things thrown in. This condition is somewhat like an endless chain, and there is no knowing the amount of complications that may arise.

Salesmen on commission if unable to sell their own models are often found selling some other make of machine in which there is a good "rake-off" for them. Salaried salesmen of the right kind usually have been found to stay longer than those on commission, and no difficulty has been experienced by their showing lack of interest in making sales. In regard to larger commissions for the agents, the statement was made that usually in a similar way an exceptionally large percentage when given by the manufacturer to the agent is used as a lever to cut prices, the agent feeling that he can afford to sacrifice a little in order to make sales, with the inevitable result, that there is immediately trouble with the other agents who have thus been undersold.

Foss-Hughes Motor Car Co.

The Foss-Hughes Motor Car Company began at 201 North Broad street, in November, 1905, as Philadelphia agents for the Pierce, Cadillac and Baker Electrics. Both Mr. Foss and Mr. Hughes had had previous experience in selling cars, both having been with the Pope Motor Car Company from the very first, as Boston and Providence agents respectively.

The first cars were not on the show floor until January 27, 1906, but their first sale, a Pierce Great Arrow, had been made in December, 1905, and seven more cars were sold before the new firm had one single car to show. The sales have increased rapidly, the total number for 1906, being 172. This success is attributed, first, to the good quality of the cars handled, and, secondly, to the close attention paid to the requirements of purchasers after a sale was made and money paid. In all cases the demands for repairs and instructions and general aid and assistance was promptly attended to. Daily advertising was used continually.

The demonstrating was incessant in the first year, but is now much less, the Pierce, Cadillac and Baker cars being now well known and generally accepted as standards in their respective classes.

The principal points emphasized to influence new trade are, excellence and reliability of cars handles, and the efforts of the firm to keep cars on the road and in satisfactory condition after they are paid for. That their theory is sound enough to bring results, is shown by the fact their sales to April 25, amount to $417,957.92 for 1907, or nearly four times the sales totals for the first four months of 1906. A blank accessories list-form, which is filled to suit each individual car sale, is used and submitted to the customer for approval, so that the buyer need not be caught on the road without things he needs to have. One customer ordered the complete list suggested for a Pierce Great Arrow, total value $757.

Nothing can go further towards satisfying a car owner than a full road equipment, and no car driver can easily avoid a friendly feeling for the selling agent whose thoughtful anticipation enables him to triumph over unexpected contingencies on the road.

J. W. Wilcox has been elected president of the Automobile Dealers' Association of Southern California, to succeed A. J. Smith, who was prevailed upon to accept the berth of vice president. Leon T. Shetler was re-elected secretary.

Retail Notes

Auburn Automobile Company, Auburn, N. Y., has taken possession of its new garage on Water street.

Akron Automobile Garage Company have purchased the Huber property on Buchtel avenue near South Main street and will erect on the lot a large garage, 165 feet by 70 feet wide.

Auto Transit Company of Philadelphia, Pa., let contracts for the erection of two garages, one at Thirty-first and Dauphin streets, covering 82x166 feet, and the other at Thirty-first and Nevada streets, which will be 128x168 feet.

Browne-Frund Motor Co., will handle the Mitchell cars in Milwaukee, Wis., at 230 Wisconsin street.

Bellefield Motor Company of Pittsburg, Pa., has taken the agency for the De Luxe cars.

Bullard Garage is the name of the new garage which was recently opened on Putnam avenue, west, Greenwich, Conn.

Brewster, J. B. & Company, Forty-ninth street and Seventh avenue, New York city, manufacturers of carriages, have made arrangements for the agency of the Acme car, manufactured at Reading.

Bellinger, Charles H., garage, on Lander st., Newburg, N. Y., is now open for business.

Calhoun, John E. & S. F. Bancroft, formerly connected with the Motor Car Supply Co., of Chicago, have formed the Calhoun-Bancroft Co., in Seattle, Wash., where they will handle several well-known cars.

Capitol Hill Garage, 615 B street, Southeast, Washington, D. C., has been appointed Washington agent for Rambler and Mitchell cars.

Crane Automobile and Garage Co., of Providence, R. I., is making ready to build a garage on the south side of Potter avenue, near Hamilton street, that city.

Columbus Buggy Co., of Columbus, Ohio, manufacturers of the Columbus electrics, has established an agency in Ponce City, Porto Rico, with Mr. Robert Graham.

Continental Auto Mfg. Co., manufacturers of the Continental cars at New Haven, Conn., will soon establish a branch in New York City on Broadway, near 52d street.

Case, Harry, Logansport, Ind., garage business has been purchased by Arthur and Herbert Dunn.

Camden Auto Exchange Company has been incorporated with $25,000 to store, repair and sell automobiles in Camden, N. J.

Doll, Augustus, has been appointed sole agent for York and York county for the Columbia automobile, manufactured by the Electric Vehicle Company of Hartford, Conn.

Dulmage-Rose Auto Company, composed of L. H. Rose H. O. Bell and W. S. Dulmage, have secured the large garage on Second avenue, between Jefferson and Adams streets, where they will handle the Haynes cars.

Dragon Automobile Co., of Philadelphia, Pa., in addition to their factory, they have established headquarters at 143-145 South Broad street, this city.

Electric Garage Company has recently incorporated and leased a one-story building at 1920 Farnam street, Omaha, Neb.

Eagle Repairing Co., New York, has removed to larger quarters at 1780-82 Broadway.

Goelet, Robert, is erecting a large six-story garage in New York City, at the northeast corner of Broadway and Sixty-fourth street.

Houpt, Harry S., of New York City, has secured headquarters at 139-141 S. Broad street, where he handles the Thomas line of cars, formerly handled by the United Motor Car Co., 215 N. Broad street.

Hamilton Garage and Motor Co. has opened a garage at 162-164 Bullsferry road, Union, N. J. The company has the agency for the Detroit and American.

Kirk Bros., Automobile Co., 915-917-919 Jefferson avenue, Toledo, Ohio. Ezra E. Kirk has resigned and H. W. Fraser has been elected president and director to fill the vacancy.

Lewis, Jr., H. H., of Fort Worth, Texas, has been appointed agent for the Rainier car for the entire State.

Morley, James, of Los Angeles, Cal., has closed a contract for the agency of the well known Matheson car.

Moseley-Haigler Electric Co. has opened an electric machine shop at 308-310 Lee street, Montgomery, Ala. A specialty will be made of automobile repairing.

Mercedes Import Co., of Philadelphia, southeast corner of Broad and Race streets, agent for the Mercedes car, has been succeeded by a new company known as the West-Stillman Motor Car Company. Mr. Stillman, manager of the former company, will also be manager of the West-Stillman Company.

Motor Transfer Company, Inc., Richmond, Va., has removed to its new garage at 605-607-609-611-613 West Broad street.

Moeller & Larson have etsablished a garage at 1023 First street, La Salle, Ill.

McAfee, A. L., has leased the new garage on West street, Healdsburg, Cal.

McCullogh, R. J., Wheeling, W. Va., is building a new garage at Sixteenth and Eoff streets, 100x70 feet, with accommodations for 50 cars. A fully-equipt repair shop will be installed and kept open night and day.

Ollier & Worthington is the name of a concern recently organized as manufacturers' agents in Los Angeles, Cal.

Pope Auto Company is the style of the new concern selling Pope Hartford cars at Newark, N. J. The garage is located at Cedar & Halsey streets.

Parlman, L. H., 1871-1875 Broadway, New York City, has secured the New York agency for the Aerocar.

Rosenberg, Louis, with temporary headquarters at Broadway Central Hotel, Greater New York, has been appointed representative for the George W. Dover Co., 80 Clifford street, Providence, R. I.

Standard Garage Motor Car Company, of Scranton, Pa., have taken the agency for the Waverly electric automobiles.

Shaffer, S. N., has opened a garage and repair shop on Main street, St. John, Mich.

Smythe, Robert A., Rockford, Ill., agent for Pierce & Maxwell cars, has broken ground for the erection of a new 70x35 feet garage, to be two stories high.

Swampscott Garage, Swampscott, Mass., has been purchased by Edwin L. Brown, who will conduct it under the name of Swampscott Auto Station. He has the agency for the Mitchell line of cars.

Southern Automobile Company is building a one-story brick building at Mobile, Ala., located at 3 South Government street.

Seattle Automobile Company, of Seattle, Wash, has moved into its new garage at 1423-1425 Tenth avenue.

Stamp, Jason, of Wheeling, W. Va., is building a large garage at Sixteenth and Chaplin streets.

Sport's, Ltd., of New York, city agents for the Royal motor cycle, the R. S. motor cycle and dealers in automobile, motor cycle and bicycle accessories and supplies, have moved from 1775 Broadway near Fifty-seventh street, to 2049 Broadway, near Seventy-first street, where they have much larger quarters.

Slater & Swanson have broken ground on Holman street, Attleboro, Mass., for the construction of a garage. It will measure 30x40 feet.

Taylor, Charles S., of Great Barrington, Vt., has opened a garage on Railroad street, which has a capacity of about 25 cars.

Titman, Leeds & Company, of Philadelphia, agents for the Studebaker & Matheson cars, have also secured the agency for the Pope line, formerly handled by the Quaker City Automobile Co.

West, Walter S., Ballston Spa, N. Y., has entered into partnership with his brother, George West, in the garage business located at Front street and Milton avenue.

Cimiotti Bros., agents for the Mora, Corbin and Waltham-Orient cars, are the latest local dealers to join the New York Automobile Trade Association. The association has just established a collection department for the benefit of its members, and has under consideration the organization of an Employment bureau thru which members may secure reliable salesmen, mechanics or chauffeurs.

W. B. Hurlbert, for the last three years manager of the New York branch of the Packard Company, has resigned and associated himself with the New Garford Motor Car Company, of New York. The latter concern is capitalized at $300,000 and will handle the product of the Garford Company, of Cleveland and Elyria, which concern has begun the construction of a high-class automobile. Mr. Hurlbert is president and general manager and Mr. Teaboldt secretary and treasurer.

F. J. Pardee, sales manager of the St. Louis Car Co., has resigned.

The Winton Motor Carriage Co., of Cleveland, O., will, on September 1, open its own branch house in San Francisco. The new building is extremely spacious, occupying the territory on Van Ness avenue between Birch and Grove streets. Charles M. Brown, who has scored such a success as manager of the Chicago branch, will be manager of this new branch. The San Francisco branch is the tenth established by the Winton Company, the others being located in London, New York, Boston, Philadelphia, Pittsburg, Cleveland, Detroit and Seattle.

Experience of Commercial Motor Car Users

Six "White" Steamers Replace Thirty Horses

The Sol Mier Co., of Lingonier, Indiana, are using six White steamers in the livery business, having by the adoption of motor cars displaced about thirty horses and 15 carriages. The 2-horse teams were able to cover only about 50 miles a day, while the motor cars cover as high as 200 miles, carrying loads weighing up to 800 lbs. The horse-drawn outfits were of course unable to cover anywhere near the area that the cars operate in, as the cars cover a radius of 200 to 300 miles. This concern considers the motor car outclasses the horse vehicle three hundred per cent. They care for the cars at their own garage.

Gasoline costs them from two to three dollars per day per car, and lubricating oil 60 cents to $1.20. Repairs and new parts run high, the figure they quote being $200 per month for each car. They pay operators $100 per month and helpers $2 per day. They claim that cars depreciate 60 per cent. per annum; that they should be made stronger thruout and the engines improved. In spite of these statements, however, they say that the motor car is away ahead of the horse-drawn vehicle for their purposes.

Motor Cars Deliver Brooklyn "Daily Eagles"

In addition to using 17 one-horse single wagons five two-horse double-platform wagons and one extra large two-horse newspaper van, the "Brooklyn Daily Eagle," of Brooklyn, N. Y., is using two Locomobiles, one Pope-Toledo, two Knox cars and one Columbia Electric. For delivery of the Sunday Eagle three large box trolley cars, in addition to wagons and automobiles, are used.

Each automobile makes an average of 21 miles per day and cover a radius of about 10 miles. The gasoline cars cost $3500 and up, the electric $1000; average monthly cost of gasoline is $11 for each car; lubricating oil $1.25 each. They store their own cars. The operator's wages are $100 per month and the helper's wages $40. They figure the cars depreciate about 12½ per cent. in value in a year.

The horses cost $250 each; wagons, $600; set of harness, $60; care and feed of each horse, $15; shoeing, $2.50 each; cost of repairs to each vehicle, $5 per month; horse driver's wages, $69.60.

The Pope-Toledo which they use has a capacity of 1500 pounds—1000 Sunday papers or 3000 daily papers and a speed of 50 miles per hour.

The two Knox cars are of the two-cylinder delivery truck type, 20 H. P., 3000 pounds capacity each—3000 Sunday papers or 9000 daily papers; speed, 20 miles per hour.

The Olds is a two-cylinder water-cooled delivery wagon. Its capacity is 2000 pounds—2000 Sunday papers or 6000 daily papers; speed, 25 miles per hour.

Their 15-20 H. P. Locomobile has a capacity of 1000 Sunday papers or 3000 daily papers and is capable of a speed of 40 miles per hour. The total average monthly expense for running one of their autos for one month is $12.25, as against $22.50 for keeping a horse and team.

Can Make Much Longer Trips and Prompter Deliveries

According to the experiences of M. O'Brien & Son, 208 Wabash avenue, Chicago, Ill., with the commercial motor car, horses will soon be forced to take a back seat.

Their first car was bought in 1902 from the Chicago Motor Vehicle Co., and was run all thru the winters of 1902, '03, '04, '05 and '06 with practically no trouble at all. The total cost of maintenance of one two-horse wagon for twelve months, including board, shoeing, veterinary, repairs to wagon and harness and painting, was $581.00, monthly average, taken on a three-year basis, was $48.42.

The total cost of maintenance for the Chicago Motor Company car for twelve months, including board, gasoline, lubricating oil and repairs to machine and tires and painting, was $512.56. The monthly average for three years was $42.72.

Their present motor car they purchased one year ago from the Kansas City Motor Car Co., and state that it has been very satisfactory. We quote herewith their own statement regarding the superiority of the motor car:

"As a general proposition the automobile has proven itself much more satisfactory. We can easily do the work of two wagons and can make much longer trips. Our de-

RELIANCE MOTOR TRUCKS

For Freight and Passenger Service.

¶ In successful operation under all kinds of conditions and service in all parts of the country.

¶ Sold under a liberal guarantee by a company in position to back it up.

¶ Manufactured complete in our own large plant which is devoted exclusively to the production of high grade commercial vehicles.

¶ Not an evolution from a pleasure vehicle, but designed strictly along truck lines with a surplus of strength in all parts.

¶ One man and a **Reliance Truck** will do the work of three men and three horse-drawn trucks, with an operating cost about equal to one horse-drawn truck. (We give you data and names of users to prove it.)

Write for catalog, and state kind of service in which you use trucks.
Some good territory open for responsible agents.

Hosted by Google

RELIANCE MOTOR CAR CO.

liveries are more prompt. We cannot do without one now and would not think of going back to horses again. The gasoline motor car is without question on its way, and we believe that all commercial houses will be forced to adopt them."

"The two principal drawbacks are the carelessness and negligence of operators and the fact that most cars are greatly overloaded, which naturally puts a very great strain on the engine. It seems almost impossible to impress this point upon the users of these vehicles. If you can obtain a good operator and can personally watch the car yourself, at least to some extent, the commercial car is bound to prove an economical proposition."

Using Motor Cars for Hauling Safes, Boilers, Etc.

The Rochester Carting Co., Rochester, N. Y., is using two commercial cars for hauling general freight, safes, boilers and all kinds of machinery.

The cars are electrics, manufactured by the Vehicle Equipment Co., of Brooklyn, N. Y., and cost $3000 and $4000 respectively. The cars carry loads of 1-3 and 1-5 tons respectively. The cost of charging these cars is 40 cents per day each. The average monthly cost for repair work and repair parts is $75 each. They store their own cars. Operator's wages are $14 per week. They figure that a car depreciates 20 per cent. in value in a year.

The motor cars now employed replace 4 horses and 2 trucks, two horses being used to each truck. Average weight of load carried was 4 tons. The trucks cost $400 each; horses $250 to $300 each, and harness $75.00 per set. Average monthly cost of shoeing each horse was $1.50; repairs to each vehicle $10.00; weekly wages of driver $12.00. The depreciation in value in a year is also figured at 20 per cent.

The most needed improvements suggested by their experience are better tires and batteries. They state that the advantages of the motor car over the horse vehicle depend on what they are used for. They claim the advantages for freight work are many if it were not for the cost of maintenance.

Fire Company Will Increase Motor Propelled Equipment

Radnor Fire Department, Wayne, Pa., have in use a motor propelled combination fire apparatus and will shortly add a motor fire engine to their equipment, being highly pleased with the success attending the use of the combination wagon. The two cars will displace 5 horses and the saving will be about $55 per month over the old method.

This fire company is entirely satisfied with the vehicle they are now using and have no improvements to suggest. Of course they care for the machine at the fire house. As would be expected their service is much more effective, being quicker, than the old outfit.

The car they now use is a 20 H. P. D 6 Knox chassis with suitable body for their requirements. It carries a load of from 2000 to 2500 lbs. The cost of operation includes $4 per month for gasoline, $2 per month for lubricating oil and $1 per month for ignition battery charging. The car averages 8 to 10 miles per day and operates over a territory of 24 miles radius.

Commercial Vehicle Notes

The regular schedule of the recently established automobile line between the Cumberland Hotel, Ocean City, N. J., and the Stockton Hotel, Cape May, went into effect July 30.

An automobile street car line is proposed for the city of Waterloo, Ia., and its promoters have asked a franchise of the City Council.

It is reported that the Manhattan Transit Company, which owns franchises for stage and 'bus lines thruout New York City, will begin September 1 the operation of a line of gasoline auto 'buses from Cortlandt street ferry across the Brooklyn Bridge to the Flatbush avenue station on the Long Island Railroad. The company will also run a line on Fifth avenue, from One Hundred and Twenty-fifth street to Fourteenth street, and thence across town on both East and West Fourteenth street, and from Fourteenth street down Broadway to the City Hall and across the Brooklyn Bridge to the Brooklyn Borough Hall. Transfers will be issued from one line to the other.

The Salvage Corps, of St. Louis, Mo., will be furnished with an automobile wagon for the corps' use.

Three motorcycles have been purchased by the Chattanooga (Tenn.) Electric Light and Power Co. for the use of its linemen in repairing broken wires.

Motor 'buses are to be operated between Kirkland and Fall City, Wash.

Chidsey Express Company, of Elizabeth, N. J., has placed an order for twenty Rapid Motor delivery wagons.

Charles A. Stevens & Co., dry goods merchants, of Chicago, Ill., were the first to use commercial buckboards in that city, having placed in service three Orient buckboards in their delivery service.

The Steelton Store Company has recently purchased from the Harrisburg Automobile Company a 6000-pound Logan truck.

The Board of Education in New York city has authorized the expenditure of $4500 for the purchase of a motor truck to transport school supplies.

The Mogollon Motor Road Company has been organized with a capital stock of $50,000 and will establish a motor car service between Mongollon mining district and Silver City, N. M.

The Punjab Motor Transport Co., of India, has recently placed in service ten 30-horse power White steamers, fitted with wagonette bus bodies.

Morton Truck and Storage Co., of Toledo, Ohio, has recently placed in service a Studebaker electric truck for the hauling of pianos for private parties and Whitney & Currier.

Thomas Keery, Sr., proprietor of the Hancock Transfer Co., has purchased a large automobile, capable of carrying 20 passengers, for use on the transfer route between Cadosia, O. & W. depot and Hancock village.

Alex. Campbell Milk Company, of Brooklyn, N. Y., is using a fifty-horse power Mack, five-ton gasoline truck in transporting milk in cans to Richmond Hill, Coney Island and Jersey City.

Motor Cycle Department

The F. A. M.'s Annual Meeting a Great Success.

The 1907 annual meet of the Federation of American Motor Cyclists, commencing with an endurance run from New York to Providence and ending with the annual meeting of the organization, on August 3, was a great success not only as an enthusiastic trade meet, but as an advertisement of the durability and efficiency of the motorcycle.

THE ENDURANCE RUN.

Fifty-five contestants started in the endurance run, five of the 60 original entrants having failed to appear. The start was made from Broadway and 88th street, New York City, at the break of day on Tuesday, July 30, four contestants being started at a time with one minute intervals between them.

Of the 55 starters, only one completed the endurance run, the hill-climb and economy test with a perfect score. This was B. T. Barrows, of Springfield, Mass., who rode a 2¼ H. P. Indian. Tied with him when they reached Hills Grove track outside of Providence were three other contestants of Class A, viz., F. A. Baker, Brooklyn; G. N. Holden, Springfield, and J. A. Schleicher, of Mt. Vernon, N. Y., all riding 2¼ H. P. Indians, but in the economy test these ties were obliterated, and Barrows was left the only perfect score man, and consequently winner of the diamond medal in Class A, single cylinder machines.

In Class B, multicylinder machines, A. Cook, of Hammondsport, N. Y., riding a 5 H. P. Curtiss, won first place, with a score of 998 points to his credit, having lost two in the economy test.

Honor medals in Class A were won by 10 other riders besides the perfect score men, and in Class B there were four honor men, including Cook.

It was the hill-climb and the economy test that cut down the number of perfect score men. Disregarding the points lost in these two events of the endurance test, there were 34 perfect scores, eight of whom, four in each class, survived the hill-climb with unimpaired scores.

The first to meet with trouble was Dr. J. P. Thornley, riding an Indian. He was so far behind the schedule at the first control, Poughkeepsie, owing to a bruised leg due to a bad fall, that he continued to Providence by rail. T. J. Deupree, on a 4 H. P. 2-cylinder Indian, was out of the running after less than three miles traveling because of exhausted ignition cells and, later, carburetor trouble. Tho hopeless of making a showing in the scoring, he afterward resumed the trip and completed the run to Providence alone. E. Y. White, on a machine of his own make, also had ignition trouble, his magneto getting out of order before he had covered 15 miles. J. F. McLaughlin, on a 3¾ H. P. N. S. U., met with an unusual accident before reaching Poughkeepsie; the stand fitted to his machine having become detached, ripped out the spokes of the rear wheel. He returned to New York, got a new wheel and went by a short route to Springfield, where he arrived that evening. Two others also went down in this first section of the run, E. Brereton and H. Jarmie, both riding R-S machines. They abandoned the run near Peekskill, the former because of ignition trouble and the latter because he had lost so many points by staying to help Brereton, who was from the same town.

The roads got worse after Poughkeepsie was past, being hilly and, beyond Lenox, soft and rough. On one of the hills, George A. Snow, driving an R-S, had a bad fall and was laid up two days with a lame back in consequence. Between Poughkeepsie and Springfield nineteen men were penalized for various causes. Three of these received further penalization between Springfield and Worcester besides one who had carried a perfect score thus far, and three dropt out of the race. Three more got penalties before reaching Providence and three dropt out.

THE HILL CLIMB.

Thirteen of the perfect score men received penalties in the climb up Morley's Hill, which is a succession of inclines ranging up to 18 per cent. The course covered about 300 yards. Speed was not a factor in this part of the contest, but penalties were imposed for pedaling or stopping.

THE ECONOMY TEST.

The "endurance test" portion of the meet ended with an economy test on Hills Grove track on the outskirts of Providence. Fuel tanks and carburetors were emptied and each contestant was furnished with one pint of gasoline, after which they were all sent off in batches of eight or ten and required to maintain an average speed of 15 miles per hour. Bar-

Hosted by Google

rows, one of the few perfect score men at this stage, kept up his good work in the economy test, and, by covering 24 miles 3490 feet on his pint of fuel, won first place in the 1907 run. In the multicylinder class Hedstrom, on a 4 H. P. Indian, took first place, running 15 miles 925 feet. As he had lost 50 points in the hill-climb, however, his good work in the economy test cut no figure in his final score, first place in this class going to Cook, who, tho he lost two points in the economy test (going 11 miles 4852 feet) had a perfect score up to that time.

Following are tables of machines, weights, penalties, etc., of the 26 finishers, in Class A, and the 11 finishers in Class B:

The distance covered by the two-days' endurance run is 305.1 miles, divided into four controls, as follows: New York to Poughkeepsie, 78.3 miles; Poughkeepsie to Springfield, 122 miles; Springfield to Worcester, 52 miles, and Worcester to Providence, 52.8 miles.

ONE-MILE TRIALS.

Preceding the handicap road race on Blackstone Boulevard, on Thursday morning, 1-mile time trials were run off with the machines divided into two classes, one of not over 30½ cubic inches piston displacement, and the other of not over 61 cubic inches piston displacement. In both classes George H. Curtiss won in 56 4-5 and 51 1-5 seconds, respectively. He, of course, rode his own make of machine. W. H. Wray, with a 14 H. P. Simplex-Peugeot, in a free-for-all, did a mile in 44 3-5 seconds. These trials were on a straightaway course on the boulevard.

THE ROAD RACE.

On Thursday morning, August 1, a road race was held on Blackstone Boulevard. This event was won by J. S. Seidell with a 3 H. P. "R-S." The distance covered was 19.8 miles, six times around a 3.3-mile circuit, and Seidell made it in 29 minutes, 10 seconds, having had a handicap of 6 minutes, 40 seconds. The second man, B. A. Swenson, on a 2¼ H. P. Indian, finished in 28 minutes, 5 seconds. He had a 5-minute handicap. Peter Cox, riding a 2¼ H. P. Indian, finished third, time, 29 minutes, 50 seconds; handicap 5 minutes. Time prizes went to Stanley T. Kellogg (3 H. P. Indian), Chas. W. Van Sickle (4 H. P. Indian) and Swenson. Kellogg's time was 26.05 and Van Sickle's 27.39.

The course is smooth and gently undulating—ideal for a road speed test. Twenty-six contestants started, handicaps ranging up to 10 minutes.

G. H. Curtiss, a scratch man, had an accident in the first lap that put him out of the running. His carburetor leaked and the gasoline caught fire, for a time threatening serious damage to Curtiss himself as well as to his machine. Howard Wray had the same experience with his 7 H. P. Simplex-Peugeot.

Fifteen place prizes and three prizes for

M. M. for 1908

This season we satisfied our customers with prompt deliveries, and shall continue this policy.

Our 1908 Models are now ready for immediate delivery. Following are brief specifications of the regular 1908 machine.

26 in. wheels, 2½ inch tires, frame dropped at seat post joint, 20 inches high; rims nickel plated with high finish, color bright vermillion; option, black or M. M. blue. The vermillion finish together with full nickeled rims and fuel tank make the handsomest machine ever produced.

Highest quality Barnes, endless, mineral tan belt, detachable through back stay of the rear jaw by simply removing one bolt and nut.

Cupped pet cock on cylinder head, together with priming device for priming engine with gasolene direct from tank by pressing a button, is a most ingenious appliance, and will be hailed with delight by those who have had trouble starting their machines in cold weather. This device also enables the rider to get gasolene for any purpose desired, such as cleaning plugs, valves, timers, etc.

This combination of 20-inch frame and 26-inch wheels enables any rider with 30-inch legs to put both feet on the ground when sitting on the saddle, which means perfect comfort at last for the short-legged rider.

Agents loose no time in renewing your contract for the sale of the M. M. for 1908.

TRACK RACES THURSDAY AFTERNOON.

On Thursday afternoon races were held on Hills Grove half-mile track, which had soft spots here and there, and a dusty surface. Several riders narrowly escaped injury in speeding on the curves of this small track. A sad and fatal accident marred the day's sport. J. L. Pickering had a fall which caused a fracture of his skull and ended in his death on the following Sunday.

The F. A. M. 2-mile national championship was won by Walter Goerke riding an Indian in 3 minutes 14 2-5 seconds. The mile free-for-all went to George H. Curtiss (Curtiss), time 1.33 2-5. A 2-mile open race was run in heats, three persons qualifying for the final, which was won by Stanley Kellogg (Indian); time 3.10. 5-mile handicap race was won by Peter Cox (Indian), time 7.45; handicap, 0.24. J. J. O'Connor on a 1¾ H. P. Indian won the one-mile novice race in 1.54 2-5.

FRIDAY MORNING HILL-CLIMB.

The motorcyclists tried for honors on Francis street hill on Friday morning, about one dozen participating. There were two classes in this event, one for machines of 30½ cubic inches piston displacement or under, and one for those of 61 cubic inches displacement or under. The hill is 200 yards long and rises at an angle of about 8 per cent. Only one machine could be sent up at a time, as the trolley cars were running up the hill and there were other drawbacks, such as a lack of police service. Curtiss made the climb in 11 3-5, winning first place in the first class, and Kellogg won in the other class, time 10 minutes flat. He used a 5 H. P. Indian. In a free-for-all race up this hill Wray ran his 14 H. P. Simplex-Peugeot up in 10 2-5 minutes. In this free-for-all Curtiss had a bad spill, in which he received some bad bruises and abrasions.

FRIDAY AFTERNOON.

Racing was continued on Friday afternoon at Hills Grove track, when the one and 10-mile national championships were run, both going to Kellogg, time of the 1-mile 1.37, and of the 10-mile 15.33 2-5. Kellogg also won the 3-mile open race for single cylinder machines in 4.38 4-5, and the 5-mile free-for-all in 7.38 2-5. The 10-mile handicap was won by Charles Van Sickle (Indian), time 16.28 4-5; handicap 25 seconds. During the running of this race Goerke collided with Cox, who was remounting his machine after a spill. Cox was badly injured, and Goerke got a bad cut in the forehead. The crowd swarmed on the track and the other contestants had to slow down. There was a 2-mile race for Rhode Islanders who had never won a first prize, and this was won by A. Heilbron on an Orient machine. He had a walkover. Time, 4.34 1-5. The proposed 50-mile team race was not run.

THE ANNUAL BUSINESS MEETING.

The annual meeting was scheduled for 8 P. M. August 3, but as many members were leaving after the races on Friday the hour was changed to 10 A. M. R. G. Betts was elected president for the ensuing year; H. J. Weyman, secretary; Geo. B. Gibson, treasurer, and the following vice-presidents: for the Eastern District, W. A. Suddard; Southern District, Edward Y. White; Western District, Irving R. Hall; Pacific District, R. H. Holmes.

In his annual report, President Betts recommended a change in the present plan of governing by districts with full appointive power vested in the vice-presidents of the respective districts. He suggested placing the appointive powers in the president. A motion was duly passed authorizing the appointment of a committee of three to plan a new method.

The treasurer's annual report showed the balance in bank to be $1402, of which the four districts have to their credit $771.40.

According to the secretary's report the membership is 1116, scattered over 36 States, the District of Columbia and Canada. Of this total, 792 members hail from the Eastern District.

A very encouraging report was rendered by the Competition Committee, showing that during the past year the registrations had increased fourfold and the sanctions twofold over the respective figures for last year. The chairman of this committee recommended, and his recommendation was adopted, that the present rule in regard to professionals be changed so that all professionals in other sports must also be rated as professionals if they enter motorcycle contests.

An appropriation of $200 was made as a testimonial of the service and devotion of H. J. Weyman, who has so faithfully served as secretary for some time. A motion was also past to appropriate $75 for the purchase of a testimonial souvenir for Chairman Douglas, of the Competition Committee, but he declined the honor on the ground that such action would establish a bad precedent.

The annual six-day bicycle race will be held in Madison Square Garden, beginning November 2.

Successful and Profitable Cycle Convention at Atlantic City

The annual convention of the cycle trade —the second annual mid-summer meeting of the Cycle Manufacturers' Association, the Cycle Parts and Accessories Association and the National Association of Bicycle Jobbers —held August 6 to 9, at Atlantic City, N. J., proved to be not only a very successful and inspiring gathering, but a much more satisfactory and profitable one than was expected. It renewed the enthusiasm of the members of the several associations present, and the coming years will no doubt show much increase in business and improvement in methods which had their inception in the Atlantic City gathering. Pleasure trips and functions were sandwiched in between the business meetings, so that while the trade's affairs were thoroly discussed, the desire for social recreation was not left unsatisfied.

W. H. Crosby, of the Crosby Co. addressed the gathering on the subject, "Trade Rocks and Shoals to be Avoided;" P. R. Robinson, of the New York Sporting Goods Co., on "Follies and Fancies to be Overcome;" E. S. Fretz, of the Light Manufacturing and Foundry Company, on "The New Opportunity and Its Demands," and E. L. Rosenfeld on "How to Regain Foreign Export Business."

The pleasure part of the program included, as one of its star features, a bowling contest held at the Columbia alleys, and participated in by four teams picked from the many who attended, the teams representing respectively the three trade organizations and the Traveling Salesmen. The highest scores in the trial games were made by the C. P. A. A. team and the Salesmen's team. These two teams then played a game of five frames to decide the leadership. The Salesmen proved the better bowlers in the final, score, 740. Detail scores follow:

TRIAL GAMES.

C. P. and A. A. Team—Wood (captain), 201; Price, 155; Mesinger, 86; Palmer, 118; Smith, 126; Heller, 134; Griswold, 111; Mossburg, 64; Gorton, 112; Wainwright, 123. Total, 1230; high-score man, Wood, 201.

Salesmen's Team—Edgar (captain), 88; Hill, 102; Buzby, 164; Snowman, 126; Field, 97; Hamilton, 111; Irland, 162; Page, 123; Brown, 89; De Silva, 141. Total, 1203; high-score man, Buzby, 164.

C. M. A. Team.—Schack (captain), 124; Schwinn, 69; Maguire, 107; Fretz, 68; Surre, 81; Wayler, 89; Lonn, 82; Cox, 155; Robie, 122; Ash, 113. Total, 1010; high-score man, Cox, 155.

Jobbers' Team—Willis (captain), 94; Robinson, 94; O'Dell, 56; Gibney, 63; Nock, 72; Leng, 129; Grady, 95; Alexander, 83; Stokes, 173; Voorhis, 81. Total, 940; high-score man, Stokes, 173.

FINAL. (Five frames).

Salesmen's Team—Irland, 81; Hamilton, 77; Field, 83; Snowman, 55; Buzby, 125; Hill, 48; Edgar, 57; Page, 84; Brown, 48; Stokes, 82. Total, 740; high-score man, Buzby, 125.

C. P. and A. A. Team—Gorton, 71; Anderson, 59; Griswold, 51; Cox, 48; Smith, 63; Palmer, 53; Mesinger, 46; Price, 73; Wood, 93; Wainwright, 69. Total, 626; high-score man, Wood, 93.

The bowling proved the most enjoyable feature of the recreation end of the program. Fully 150 persons attended, and both players and spectators were very enthusiastic. While several of the players were inexperienced, several were crack bowlers, as their good scores show. Wood, Price, Palmer, Smith, Heller, Gorton, Buzby, Maguire, Cox, Robie, Ash, Irland, Hamilton, Snowman, Page, De Silva, Leng and Stokes, all made scores of over 100, Wood passing the 200 mark by one and Buzby proving the high-score man on the Salesmen's team in both games.

SPEECHES, CLAM BAKE, ETC.

The address delivered by P. R. Robinson, of the New York Sporting Goods Company, was stirring and interesting. He reviewed in a forceful manner the several "follies and fancies" that threaten the cycle trade, among these the habit of allowing disparaging remarks about the cycle trade to go unchallenged and undenied; the lack of argument and information in manufacturers' advertisements; the unfair treatment of jobbers by manufacturers and by manufacturers' agents, who sometimes sell to dealers at jobbers prices; the evil of price cutting and the danger of a lack of competition.

W. H. Crosby, of the Crosby Company, spoke on "trade rocks and shoals" to be avoided, clearly and logically bringing to the attention of his hearers several questionable methods which to him seem to threaten the welfare of the cycle industry unless sighted and avoided by manufacturers.

First he spoke of the danger of overproduction, and suggested that it might be well to take some concerted action toward limiting outputs, as is done in other trades. The second "rock" he pointed out is the habit of too high a selling price; third, loose credit; fourth, our dependence on the home market for the sale of our factories' outputs; fifth, the bad habit of delaying specifications, and thus crowding the parts and material makers, and, sixth, the rapid introduction of untried methods. His address showed that he had given the subject in hand serious and intelligent thought, which, backed up by his wide experience, enabled him to make an address that appealed to the common sense and business instincts of his hearers.

E. S. Fretz, of the Light Mfg. and Foundry Co., gave a very practical talk on "The New Opportunity and Its Demands," leading up to his main proposition by a summary of the history of bicycling and pointing out, that with the bicycle business settled down on a firm basis of practical service and every-day pleasure, the opportunity was at hand to make bicycling universally popular. He advocated plenty of publicity and the encouragement of bicycle contests. His admirable speech is epitomized in the following extract from it:

"Now that the industry has assumed a more favorable situation, it is up to the

Hosted by Google

manufacturer to conserve its best interests by pursuing a progressive policy in the manufacturing and advertising and a conservative policy in holding to the supply and demand that overproduction can be controlled. Overproduction, which naturally forces price cutting, is the death knell of any industry."

The last formal address was made by E. L. Rosenfeld, a member of the export firm, Guitherman, Rosenfeld & Co. He gave some sensible suggestions as to how to regain foreign trade, and, like the other speakers, advised, practically, a return to the methods which proved so successful in former years. The gist of his remarks is summed up in his closing paragraph:

"When we give due consideration to the customs and tastes of the various foreign markets; when we study the competitive conditions existing there and give such conditions intelligent recognition; when we are progressive and aggressive and bring new articles to the attention of trade from time to time; when we select the proper selling methods and follow the same consistently and give the business when obtained the proper care and attention, then we shall find that we are making rapid strides toward regaining that fair share of the world's trade in bicycles, bicycle parts and accessories which the resources of our country and the ability and energy of our people entitle us to."

On Wednesday, August 7, following the joint session, a clambake was held at the Inlet Pavilion, at which considerably over a hundred men and women thoroly enjoyed themselves.

To Repeat Brooklyn Motorcycle Club Economy Test

The Brooklyn Motorcycle Club has voted to repeat its road economy test which was one of the most interesting and instructive events of 1905. It will be held Sunday, September 15, in conjunction with the New York Motorcycle Club. The route will be from Brooklyn to Southampton, L. I., and return, a distance of approximately 200 miles. Tanks will be sealed at the starting point, and refillings and resealings be permitted only at given places en route. Two classes—users of single and of double cylinder motorcycles—will be provided for and the best prizes a silver cup in each class, will be awarded to the private owners making the most economical performances. In addition, there will be ten or fifteen other awards. H. J. Wehman, 108 Park Row, New York, will have charge of the entry list.

Harley-Davidson Winner at Milwaukee

Two motor cycle events were included in the program of motor vehicle races at the State Fair grounds, Milwaukee, Wis., July 27, and a Harley-Davidson machine, Davidson driving, won both. One was a 5-mile event for the Esser cup and Davidson's time was 6.36. However, the special event was the 5-mile match between Davidson, on a single cylinder Harley Davidson, and George W. Lyons, of Chicago, on a double cylinder five H. P. Simplex Peugeot.

Owing to the fact that Lyons was riding a double cylinder machine and Davidson a single, the judges made an allowance of 30 seconds handicap, but this was not needed, as Davidson got in 40 seconds ahead of Lyons. Time, 6.37.

At Reading, Pa., July 26, William Bewley, on an R-S, won a 3-mile motor cycle race on a half-mile track. He made the first heat in 4.27 1-5 and the final in 4.28.

L. A. W. Assembly in Boston

The National Assembly, League of American Wheelmen, will be held in Boston, September 12, with every prospect of a larger attendance than has been seen at an L. A. W. meeting in several years. An added attraction will be the Boston Bicycle Club's "Wheel About The Hub," which will be started this year on September 13th, with a fine showing of wheelmen.

U. S. Adjutant Uses Motorcycle

To economize time as far as possible in the performance of his duties, Captain W. A. Burnside, adjutant to the commandant of the Columbus, Ohio, recruiting station of the United States army, has just purchased a motor bicycle to replace the ordinary bicycle which he has been using for a year and more. The ground occupied by the Government reservation is so great that the officers find it a great saving to employ bicycles in going about from point to point. This, however, is the first instance in which the motorcycle has been resorted to.

Labor Day Race at Milwaukee

A 25-mile bicycle road race has been arranged for Labor Day at Milwaukee, under sanction of the National Cycling Association. The manager of the event is P. J. Sullivan, from whom all information concerning entries may be obtained.

Trade Printed Matter

Frank B. Widmayer, 2312 Broadway, New York, has just issued what is one of the most complete little catalogs of motor cycle accessories in print. While containing but 28 pages, it lists a large number of specialties all of which are clearly illustrated, the cuts showing up well, as a good grade of paper with suitable surface has been used. Each illustration is numbered to make ordering easy.

One of the most prominent British motor cycle makers is Brown Bros., Ltd., of London, and their latest catalog is convincing evidence of this fact. It is very attractive and is plentifully illustrated. One page is devoted entirely to reproductions of medals won by the Brown motorcycle, containing illustrations of 22 medals. The constructive details are fully illustrated and amply explained in the text. A 3-page insert contains numbered illustrations of all Brown motorcycle parts to facilitate ordering repairs.

Picaroon Wins Marblehead Race

The Marblehead race was run July 20 for the third time, and more successfully than any time before. Every boat finished practically without a mishap and in far better time than 1905 or 1906, despite the fact that all sorts of weather conditions were encountered, including fog, rain, strong winds and a heavy sea.

The course was from New Rochelle to Marblehead, a distance of 270 nautical miles.

The race was started at 10.15 o'clock and was won by Picaroon on time allowance. Her average speed was 8.19 nautical or 9.44 statute miles per hour.

Motor boat Hopalong, a scratch boat, made the fastest time, covering the course in 30h., 42m., 35s. She took the lead at the start and was never headed.

Summary follows:

	Rating	Corrected Time.	Cor. Fin.
Hopalong, Daniel E. Hallett, Boston Y. C.	39.32	30.42.35	4
Whew, Edw. S. Welch, Boston	38.06	30.49.16	5
Picaroon, T. B. Baylies, New Bedford Y. C.	31.63	28.46.24	1
Aldred, Chas. H. Voorhes, Riverside Y. C.	30.72	29.46.19	3
Irene, S. W. Granbery, Colonial Y. C.	29.56	28.50.42	2
Argo, John Armstrong, Bridgeport Y. C.	31.80	33.02.32	7
Susie, J. B. Schmelzel, Knickerbocker Y. C.	28.30	32.27.35	6

Frontenac Club Races

The Frontenac Yacht Club, of Frontenac, N. Y., held its first motorboat races of the season July 26 and 27, over the club's triangular course.

Owing to the rough weather, the list of entries was considerably reduced by the time the races were started.

The first event was a free-for-all for boats not over 35 feet water line, distance 14 miles, or twice around the course. The starters were Damphino, Pirate, Jr., and What Next. Damphino was the sole survivor, completed the course in fair shape considering the weather and was awarded the silver cup. Time 1h., 8min., 37s.

On the second day the wind had somewhat abated, but the water was rough.

The 14-mile handicap for boats not less than 30-foot water-line was run in one heat, and the starters were Damphino, Delawanna and Pirate, Jr. Delawanna soon came in, leaving Damphino in advance of Pirate, Jr. They finished in that order, and first two obtained handsome silver trophies. The winner's time for the course was 47m., 13s.

The free-for-all on the same afternoon resulted in the prettiest contest ever run on this river, when the speedy Simplex XI, owned by W. C. Whitehead and H. Broesel, of New York, defeated Pirate, last year's champion. The boats, however, finished only 68 seconds apart, and the victory was hard fought every foot of the way. The course was 21 miles, thrice around, and the victor's time only 47m., 42s.

"Chip II" Again Wins Gold Cup Race

The Chippewa Yacht Club has again won the Gold Challenge Cup of the American Power Boat Association, making this the fourth consecutive time that this club has won the cup.

The Chip II is owned by J. Wainwright, of Philadelphia, and is the product of Messrs. Levare and Leighton, the former being the well-known boat-builder of Ogdensburg, N. Y., and the latter the maker of the Leighton engine, of Brewerton, N. Y. The races were held on the Chippewa Bay, N. Y., on August 14 and 15, over a course of 30 nautical miles. The elapsed time for the Chip II for the first heat was 1:31:06, second heat 1:30:44 and for the final heat 1:26:43. The other boats entered in the race were the "Vingt-Trois," Frontenac club; "Delawanna," Clayton club; "Stranger," 1000 Island club, and the "Pirate," of the St. Lawrence River club.

Hudson River Carnival Sept. 23

One of the greatest events for this fall is the annual Motorboat Carnival which is to be held under the auspices of the Motor Boat Club of America, on the North River, at 108th street, starting Monday, September 23, and continuing thru the week.

The American motor boat Dixie, owned by Commodore E. J. Schroeder, of the Autoboat Club of America, won the race for the International Marine Cup in Southampton water, August 2, defeating its nearest English competitor the Daimler II, by three-quarters of a mile over a thirty-five mile course.

long by 7 feet beam, and the other 25 long by 6 feet beam. The 25-foot launch riven by a 5 H. P. motor and lists at . The 30-foot size has a 7 H. P. motor lists at $500. They are capable of ds up to 12 miles per hour. The hulls e list at $250 and $275, respectively. Mr. ney also puts out a $600, 30-foot hunt- cabin launch.

The "Flying Dragoon"

high-speed motor boat, combining speed a high degree of safety, stability and fortable seating appointments, is the ing Dragoon," manufactured by the tric Launch Co., of Bayonne, N. J. The ing Dragoon" makes a speed of 20 miles hour and is driven by a 50 H. P., 4-cy- r Elco Gasoline Motor placed forward protected by an aluminum hood resting he coaning and across the bulkhead aft he motor. All motor controls are in- ed on this bulkhead, while the steering el and reverse levers are conveniently ed in front of operator's cross seat. access to the motor is allowed for in- ion and oiling.

e hull is built with oak keel and tim- hackmatack stem, rock elm frames and r planking, copper riveted to frames; rstrake of oak with guard moulding ed on this strake. The decks, transom, ing and interior finish are of mahog- Seating capacity is provided for nine

ed in leather. The fuel tank is of copper an is placed in a copper-lined compartment ope to sea aft of operator's seat.

The general equipment of the boat in cludes all absolutely necessary deck fitting such as chocks, seats, hatch lifts, socket ventilator, flag poles, acetylene searchligh with Prest-O-Lite storage tank.

"Prest-O-Lite" Marine Lighting Outfit

The Prest-O-Lite Co., Indianapolis, Ind makers of the "Prest-O-Lite" acetylen tanks, which have become quite popular i the automobile field, are now furnishing va rious sizes for use on yachts and motor boats.

Cylinders of various capacities may be ob tained, from the small one that will ligh the cabin of a small boat to the large cy inders that will supply light for the ocean going yacht for the entire season. A sailin yacht of 45 to 50 feet waterline length re quires, approximately, 125 cubic feet o acetylene per month. A cylinder 12 inche in diameter and 36 inches in length charge with asbestos and acetone, would contain 22 cubic feet of acetylene; two such cylinder would supply such a boat the entire season

For larger yachts and boats the "doubl cylinder system" is often used. A full cyl inder can then always be kept in reserve and on long cruises it does away with th inconvenience of sending a cylinder back t be recharged.

For Cleaning Auto Bodies

It's good to see how quickly Mobo removes mud, grease and dirt from an automobile body. It doesn't matter how long the car has gone without cleaning, or how thick the dirt may be—off it comes, easily and quickly if you use

MOBO

Automobile Cleanser

Not only does it remove all the dirt, but does it without marring or scratching the varnished surface, and without dimming the lustre in any way. That's Mobo style.

Mobo is composed of pure vegetable oils, and contains nothing rough to mark the smoothest surface. It is the ideal automobile cleanser.

Prevents the varnish and paint from cracking and blistering. Keeps the car looking new. It's the best sold to-day. Try it once and you'll understand why.

Put up in 3 lb. and 6 lb. cans; also in tubs, half-barrels and barrels. Can be had at the following supply house:

National Supply Co.
13 S. 17th Street
Philadelphia, Pa.

and at all good automobile supply stores in all leading cities.

Send for our Mobo booklet —"*How to Clean Well Varnish and Paint on an Automobile*" It's free.

reet, Boston, Mass., manufacture an auto-
atic folding propeller, a very real need for
ch a device having manifested itself es-
cially among users of auxiliary boats. As
rigid propeller is quite a drag on such
aft when the power is not being used, a
lding propeller is really necessary to allow
stallation of auxiliary power.

Fig. 1. Fuller Folding Propeller.

Fuller Automatic Folding Propellers have
oved practicable and durable on fishing
aft and pleasure boats for the last four
ars. They are made either with two or
ree blades and any pitch or diameter. The
ree-bladed wheels are folded in the same
ameter, of hub or boss, as the two and,
erefore, do not offer any more resistance
the water. These wheels are automatic

Fig. 2. Fuller Folding Propeller.

action, there being no levers, hollow
afts or complicated parts to get out of
der. They are made in two styles; one
r forward movement and the other for
rward and reverse movement. Where the
verse movement is used very little and
en only when maneuvering for moorings

stop on the shaft is at the forward
of the hub, as in Fig. 1. The hub revol
and the action of the screw blades op
them (the blades) immediately and they
main open as long as the propeller is
volved in that direction, communicating
ward motion to the boat.

Fig 3. Fuller Folding Propeller.

If the engine is reversed, the resista
of the blades on the water (either i
closed or partially open position) prev
the hub from moving, the after end of
shaft meeting the shoulder on the lower
of the blades, pushing them outward
thereby opening them as in Fig. 3.

This, of course, is only relative to
shaft, as it is the hub that moves. If
engine continues to revolve in that direct
the blades will hold in that position an
the engine is then started for forward
tion the blades again prevent the hub f
turning around and it moves aft on
shaft until the stop on shaft engages
stop in the forward end of the hub, a
Fig. 1, when the entire propeller again
volves as in an ordinary solid propeller

When the engine is stopped, the mo
of the boat, thru the water causes the bl
to fold. It has been found that one to t
revolutions is all that is required to
for either forward or reverse motion. T

We print on this page each month an exact statement of the number of copies printed and distributed of the preceding issue of "The Cycle and Automobile Trade Journal."

The bindery count of actual complete copies produced of the September issue was 20,091.

Of these, 20,221 pounds were mailed at pound rates, as shown by post office receipts. Each copy weighs 18¼ ounces, representing 19,302 copies, and 5,041 copies of back numbers and copies returned by news companies are accounted for, in addition to the total for the month.

We will be pleased to verify the above figures at any time to any one interested.

Mechanical Branch of A. L. A. M. Meet

At the meeting of the Mechanical Branch of the Association of Licensed Automobile Manufacturers, September 23, the subject of ballbearing motors was discussed. Mr. Frank Stearns, of F. B. Stearns Company read a very carefully prepared paper on the subject. At the afternoon session there was a report of the Tire Committee; the subject being a two part or detachable rim. There was also a report of the Test Committee on engine tests recently made at Hartford, which proved of great interest. The recommendation of the Test Committee, for a series of elaborate alcohol tests, was approved.

Coming Events

September 28-October 7.—International Automobile Show, Copenhagen, Denmark.

September 30-October 4.—Race meet and 24-hour contest; Interstate Fair; Grounds Track, Trenton, N. J.

September 30-October 5.—Daily Auto Races at Montana State Fair, Helena, Mont.

October 1-15.—Contest of Electric Vehicles, Automobile Club of France.

October 6.—Cup of L'Auto Maisons-Laffitte.

July 14.—Paris to London, Aerial Race.

The American Motor League proposes to remit to its state and local organizations two-thirds of all the dues and fees received from the members—the remaining one-third to be devoted to the purposes of the national body. This arrangement will give to the clubs a substantial share of the funds with which to prosecute the work of the League in their several localities.

Hosted by Google

Ban Placed on Racing Association

The Executive Committee of the Racing Board of the American Automobile Association adopted the following resolution, suspended the United States Motor Racing Association, and also defined the difference between a touring car, a touring runabout, and a runabout.

Resolution:

Any club of the American Automobile Association which associates itself in any way, wholly or partially, with the promotion of a race meet shall become responsible for the delivery of the prizes as stated on the entry blank, and also for the enforcement of the racing rules of the American Automobile Association.

Joseph M. Gaites, president; Fred T. Bailey, vice-president, and W. H. Pickens, general manager, all of the United States Motor Racing Association, were indefinitely suspended, together with the organization of that name, and all sanctions granted were cancelled, because of irregularities in the conduct of the race meet held at Brighton Beach, August 9 and 10.

To determine properly the exact division between touring cars, touring runabouts and runabouts, the Board announced the following definitions:

Touring Cars—A touring car shall be one provided with a tonneau and seats for at least five adults, two in front and three or more in the tonneau.

Touring Runabouts—A touring runabout shall be a car provided with two seats in front and a single permanent seat in the rear.

Runabouts—A runabout shall be a car provided with two seats side by side.

A. A. A. Officials Answer Criticisms

Officials of the American Automobile Association are coming forward in defense of the Association and its methods of management. Secretary Frederick H. Elliott, in reply to the numerous criticisms in regard to the management of 24-hour races, etc., which have been given publicity of late, said: "At the annual meeting of the Association, held in January last, the by-laws were amended and revised providing for the future management of the Association as desired by the clubs and State Associations which comprise the management. The clubs which are members of the sixteen State Associations affiliated with the A. A. A., nominate their representatives in the Board of Directors of their respective associations. The Board of Directors of the State Associations nominate one director for every five hundred members in the State body to represent the State organization in the National Board of Directors. The National Board of Directors are therefore representative of every State and elect the directors from the clubs which are unfederated or not in the State Associations. The directors of the National body elect the Executive Committee, and the Executive Committee elects the officers."

Mr. A. G. Batchelder, formerly secretary of the A. A. A., says: "I don't see how you can evolve any better form of government than to have every club represented in the meetings of the State Associations to which it belongs, and then have these State Associations elect the National Board of Directors, which then elect the National officers." . . . "A flash of criticism caused by a couple of mismanaged twenty-four-hour races is not sufficient in my mind to eclipse the real worth of the organization."

New York Motorists Organizing

About one hundred and forty-six members of the American Motor League have been appointed representatives to compose the New York State board of officers and to act as a special organization committee until the beginning of the next official year. Other appointments to complete this board will be announced later; a chief consul, vice-consul and secretary-treasurer will be named and the board will be called together at an early day to adopt a constitution and by-laws. In the meantime the chief consul will appoint standing committees and set the work of the Division in progress.

In organizing the state division, the 61 counties of New York have been divided into 10 districts, each of which will be entitled to a number of representatives proportionate to the number of League members enrolled within the district. State boards have been appointed in 36 other states, and over 1300 acceptances have been received from prominent motorists in all parts of the country who will become members of the state boards in their respective states. The membership has now been brought to a point which makes both possible and necessary the organization work, originally laid out. Each state division will have its own executive officers and state board thru which the affairs of the division will be directed. The state boards will elect delegates to the national assembly and the national assembly will elect officers of the national body and prescribe rules from time to time for its government.

To enlighten the automobile purchasing public on the mechanical construction of 1908 models and the principal changes from 1907 to 1908 cars, the American Motor Car Manufacturers' Association has engaged the services of Charles E. Duryea, recognized as one of America's leading mechanical experts, to write comprehensive mechanical data for the association's members.

Hosted by Google

A. A. A. Directors Hold Quarterly Meeting

The quarterly meeting of the Board of Directors of the American Automobile Association was held at the association's offices, New York on Thursday, September 19th, with fifteen members present. This was a record attendance for a meeting of the directors.

This meeting was by far the most important ever held by the association considering the broad scope of the questions discussed, the very encouraging nature of the different reports submitted, and the optimistic outlook for automobiling in the future.

Secretary Elliott's report shows that the total membership of the association at the present time is 18,550—made up of sixteen State associations comprising 109 clubs, 15 clubs unfederated with State associa tions, and 550 individual members. During the present administration the membership of the association has more than doubled, and the number of affiliated State associations has been trebled, and applications are expected shortly from four recently organized State bodies in the South and West.

The report of President Hotchkiss was most complete and interesting, and covered the activities of the association since the meeting of the directors in March.

The President strongly recommended such changes in the organization of the association tending to increase its revenue from members, all of which were approved by the directors and are outlined in the following paragraphs:—

Provision was made for a Technical Board to which will be referred all matters of contests of a technical character, including contests between stript touring cars, which board shall have charge of all such contests with power to make rules and enforce fines and penalties subject however at all times to the control and veto of the Board of Directors or the Executive Committee.

A special committee representative of the various trade interests was appointed to consider the advisability of sanctioning track races. This committee after conferring with the representative national bodies of manufacturers and with the affiliated A. A. A. Clubs, will report at the directors' meeting in November.

The directors approved of the position taken by the donor of the Vanderbilt Cup and the Racing Board in deciding to hold no race this year for the cup over public highways unless the course could be properly guarded by troops.

The amendments to the by-laws were adopted providing for the annual meeting of the association to be held in November, instead of December. The fiscal year was also changed to begin November 1st, instead of February 1st. There will be quarterly meetings of the Board of Directors hereafter to be held in February, April, September and November.

The directors adopted a resolution which was recommended by the Executive Board of the Racing Board, providing that any club, a member of the A. A. A., which associates itself in any way, wholly or partially, with the promotion of a race meet shall become responsible for the delivery of the prizes as stated on the entry blank, and also for the enforcement of the rules of the Racing Board of the A. A. A.

It is proposed to hold a general convention of the A. A. A. at some central point during the touring season next year, with a programme including technical contests, etc. The matter was referred to the Executive Committee.

Engineers Meet in Hartford

The Test Committee of the Mechanical Branch of the Association of Licensed Automobile Manufacturers met in Hartford, Conn., Monday, September 9. Three very important subjects were under consideration, which will undoubtedly produce some very interesting results at the termination of the experiments under way.

The use of denatured alcohol, which for some time has occupied the attention of chemical experts has been given a thoro test by the mechanical branch. At the morning session, Irving Buck, the chemical expert of the United States Alcohol Company, delivered a lecture on the subject, and submitted to the committee a report of the results of his recent experiments, which prove that alcohol may shortly be a factor in the propulsion of horseless vehicles. The committee will install a plant for making more exhaustive experiments of alcohol. It is the purpose of the committee to conduct experiments with various carburetors now on the market to attempt to adapt the use of alcohol to the present day motors. The engineers have been endeavoring thru extensive experiments to obtain the maximum results in motor construction toward a reduction of the amount of fuel consumed, and some interesting efficiency tests were conducted, shown by brake tests, heat development and fuel consumption under various piston speeds.

Part of the afternoon session was devoted to the subject of tires, and an interesting demonstration was given of the new Dow tube—a non-deflative tube. This tube is of peculiar construction. A tube in the tire is filled with a self-healing plastic material which permanently seals up the tire when punctured. The night before the meeting a test run was made between New York and Hartford. On leaving New York six punctures were made in the tire, and six nails were also placed in the tire, and left until their arrival in Hartford, when they were withdrawn with practically no loss of air.

The Working Man's Automobile

Doubtless some of those who have been following the development and trend of the automobile industry were somewhat surprised and somewhat amused at the early buggy type of machine which originated in the Middle West. These same individuals are probably even more surprised to-day to see the remarkable development of this class of motor cars. Yet this is exactly the kind of development that must be expected. These little cars, to which at first very little attention was paid, or if noticed at all, were ridiculed, have gradually but positively made their influence felt, particularly in the West, and are destined to bring about the long-looked-for, low-priced, but practical machine, which may be called the "working-man's automobile."

The ever increasing demand by thousands of people for a neat, simple, reliable car at a price ranging from $250 to $500 has been appreciated by machinery and farm implement manufacturers, and far-reaching preparations are now under way to supply this demand.

It has been said that a good car at such a price was impossible, and the makers of large luxuriously-appointed cars at once dismissed the idea of their manufacture. But the time will soon be here when they will be forced to pay attention to this type of vehicle. The best cars to-day are good for six or eight years of continued service, and as the models change so slightly from year to year, and will change less, those who already have serviceable machines will not change to a new car each year, thus the number of first car purchasers is rapidly diminishing, and it will soon be necessary to cater to a certain extent to those desiring a low-priced machine the field of buyers for which it is practically unlimited.

Automatic and special machinery for the construction of internal combustion engines have now been perfected, and such combinations as a two-cycle engine, friction change speed and solid tires can even now be serviceably built within the price limits set, and it will be but a short time before manufacturing conditions will be such as to make their construction possible at even a less cost. Of course, chrome nickel and vanadium steels, annular ball-bearings and many things which are used in high-priced cars will not enter into their construction. But these are not essential in small 8 to 12 H. P. cars not intended for speeds over 20 miles an hour. Plain felted oil pocketed bearings can be successfully employed on the wheels and air cooling also simplifies the construction. The bodies owing to well developed American machinery for this purpose can be cheaply but well built.

Already there are on the American market some twenty concerns manufacturing cars of this general type. These may be considered the forerunners of the "working man's automobile," for the time is surely coming, and is not far removed, when serviceable small cars can be had at prices which will bring them within the reach of many of the so-called working class.

Suitable Publicity Marks an Era of Progress

The progress that has been made in all the arts since the introduction of the printing press has made possible a rapid spread of knowledge, is a matter of record. The daily interchange of mechanical ideas connected with the proper kind of publicity is one of the basic and fundamental causes of the rapid growth of many of our industries. The thriving automobile industry of to-day is no exception to this general rule. The widespread publicity given the constructive features of the different makes and types of machines by the trade publications in the automobile field, is in a large degree responsible for the exceptionally rapid advancement made by our manufacturers.

In the early stages of almost every industry the narrow winded and selfish policy of endeavoring to keep secret every detail of the work, is usually followed, and as a result the progress of the industry as a whole is very slow, and necessarily remains so just as long as this selfish

Hosted by Google

course is adhered to. Each worker guards jealously the small fund of information contained in his note book until some longer-headed and far-seeing manufacturer publishes his knowledge on the subject in connection with publicity given his product and reaps his reward, as he is inevitably credited with having superior information and methods of manufacture, and, therefore, better goods than his contemporaries. The cordon of secrecy thus broken, others follow suit and an era of rapid progress is the result.

The automobile industry past the secret stage some years ago, and to-day each manufacturer vies with the other in making public the particularly advantageous and clever constructions embodied in the design of his car. Of course, this is not done until such constructions as can be suitably protected, have been patented. Yet in spite of the lessons taught by the past of other industries, occasionally a manufacturer is still found who is so wrapt up and enclosed in the dense impenetrable shell of his own conceit, that he believes his creations to be far better than those of his fellow manufacturers and persists in the ridiculous endeavor of keeping secret his methods and constructions. Fortunately for the industry, however, these individuals are nearly always very small manufacturers whose peculiar ideas, when divulged, as sooner or later they must be, are found to be far behind the alert up-to-date manufacturer who is willing to talk and benefit by an interchange of ideas.

Uniform Horse-Power Ratings

There is probably no one feature in connection with the internal combustion motor more discussed than the question of the horse-power rating of the engines by different manufacturers, and the question is still being discussed in spite of the fact that the A. L. A. M. engineers have decided on an empirical formula, based on good American practice. This formula, which is only approximate, consists simply in squaring the diameter or bore and multiplying by the number of cylinders; this being divided by 2.5. This formula takes into consideration the length of stroke, the mechanical efficiency and many other conditions, as it is based upon the performance of a large number of typical engines of different bore and stroke. It is close enough for all ordinary purposes, but is apparently a little high when applied to single cylinder engines of small bore.

Why do we wish to know the horse-power of an automobile engine? Usually for a means of comparing one automobile with another. But does the horse-power of the engine give us this means of comparison when the method of transmitting the power and the amount which may be absorbed in this transmission is absolutely ignored? This method of comparing performances is about as reasonable as endeavoring to compare the work which might be accomplished by two electrical power plants by simply comparing the capacities of the generators and disregarding the different and various amounts of resistance to be met with in the two circuits.

What is really wanted as a means of comparison is the actual amount of power delivered at the driving wheels, taking into consideration all the losses due to the various methods of transmitting the power to the point where it can be effectively used. Several manufacturers realizing this fact are giving their cars a rear wheel rating, but this instead of lessening the difficulties, simply adds complication as such a rating is necessarily apparently much lower for the same size and type of engine than the rating of the other manufacturer who is speaking simply of the power of the engine.

What is needed is uniformity in this matter, and as it is impossible to actually compare one machine with another by simply knowing the horse-power of the engine, it would seem that before long some uniform method of rating automobiles by the power output at the rear wheels will be adopted. That a standard rating of this kind is possible is beyond doubt. Of course, in determining such a standard, difficulties would be met with in deciding upon one which would do full justice to both the single cylinder low horse-power runabout and the six-cylinder runabout of seven or eight times that power, but nevertheless such a rating is not only possible, but very necessary, and it is hoped steps will be taken in the immediate future to bring about such a result.

The Demoralizing Effects of Inter-City Record Attempts

Inter-city speed records are every day increasing in number. In each and every case it is well known that the driver must necessarily break the speed laws of the several States thru which he passes. Yet these record-breaking attempts between our large cities are being indulged in more and more by supposedly reputable firms and are not by any means confined to over-ambitious individual car owners.

Such attempts are entirely wrong in every respect. Even the advertising to be gained from them is of very little value, as no reputable paper can publish as facts the results of such unattested and unsanctioned attempts. During these trials it is well known that the drivers take grave risks, to say nothing of the danger to unsuspecting road users who are suddenly met by the speeding machine.

But this is only the material side of the

Hosted by Google

question. There is also the moral aspect and its demoralizing effect to be considered. It is bad enough to have to use the highways for speed events even when the road users and public in general are warned and know what to expect, but indiscriminate and deliberate breaking of not only the speed laws but of all ordinary laws of consideration due other highway users, certainly ought not to be indulged in by automobile dealers and manufacturers.

A large part of the antagonistic feeling against the automobile is due to the reckless and inconsiderate use of the public highways by just such drivers, who have, or think they have, reason for great speed and have no time to be considerate of others. Every additional case only augments the adverse feeling and adds just so much to the clog of prejudice which interferes with the universal adoption of the automobile. To the same cause can be attributed the mass of unfavorable legislation which has been enacted. All such abuses of the highways cannot fail to re-act harmfully to the industry, the harm being many times in excess of any petty advertising advantages which might be gained. If a car really has the ability to make records, this ability can be far better shown by entering suitable contests sanctioned by the proper authorities, the results of which will be authentic.

We believe that the practice of attempting to establish inter-city records is bad from every point of view and that all the better class of dealers and manufacturers realizing the demoralizing effects of such runs will not only refrain from, but will endeavor to put a stop to, all such indiscriminate and deliberate breaking not only of the letter but the spirit of the laws.

New Alcohol Law

The Government method of handling the denatured alcohol industry will be much more liberal under the new regulations regarding it which went into effect September 1, 1907. In addition to the privilege of constructing warehouses on distillery premises, central denaturing warehouses may be constructed and operated at such points as in the opinion of the Commissioner of Internal Revenue the business interests of the country may require. Proprietors of central denaturing warehouses may transfer thereto for denaturization other alcohol produced at their own distilleries or alcohol purchased by them. Denatured alcohol may be transferred from denaturing warehouse by means of tanks or tank cars to consumers of, manufacturers using or dealers in denatured alcohol. Denatured alcohol transported in bulk thru pipes or in tanks or by tank cars will be gaged by weight. Dealers in denatured alcohol are not required to swear to an application for permit, and a permit when secured continues in force until revoked, and will not therefore have to be renewed annually as heretofore. Retail dealers in denatured alcohol are not required to keep a record of any kind. They may purchase alcohol in stamped packages of five gallons or more, or from tank wagons in quantities of five gallons or more, or they may purchase it in quantities of less than five gallons, provided it is taken from stamped packages or duly authorized tank wagons.

Trade Credit Association Secures Results

At the regular meeting of the Board of Directors of the Automobile Trade Credit Association, held September 17th at the office of the secretary, 80 Wall street, New York, a report was made that the membership had nearly doubled within the last six months. This association deserves the co-operation and active support of everyone in the industry. The regulating of credits and the collection of overdue accounts by a co-operative organization is indeed desirable in any industry, but especially so in a new one like the motor car business, where credits necessarily must be extended to firms not well established.

A report of the directors shows that a very large percentage of accounts referred to the association for collection are handled successfully, and that the members secure settlement from delinquent debtors who would not otherwise pay. The phenomenal work of this excellent association is due to the fact that it is a non-money-making organization. The directors are men who devote their time and attention to this work without remuneration, and in consequence the cost is nominal considering the services rendered. It is a self-supporting and purely co-operative association, and every manufacturer and jobber in the motor industry should be a member. The larger the membership the greater the results, and for this reason it is safe to state that the Association is just twice as strong to-day as it was six months ago, and that it is now an assured permanent factor in the motor business, and will do much to correct loose credit evils resulting from the quick growth of the automobile industry. Any manufacturer or jobber is privileged to join the association, and full particulars may be had by addressing the secretary, Mr. Franz Neilson, 80 Wall street, New York City.

An inspection of the announcements for 1908 of some of the leading American automobile manufacturers shows that prest steel will be used in many cases in place of armored wood for body building. It is understood to be lighter, stronger, and in every way an improvement.

Considerations of Motor Car Elements

HUGH DOLNAR.

(The name of the writer of these considerations is well known to our readers as a describer of new cars, and his extended experience as a machine designer and constructor gives value to his deductions and suggestions. Should any of our readers dissent from the conclusions reached in these articles, the columns of the Journal are open to all, in the full belief that free discussion and interchange of opinion is the shortest road to perfection.—Editor.)

Springs

The one motor car element which nobody can make just exactly right is the springs.

Springs are now very much better than ever before, and a considerable number of the 1907 Glidden Tour contestants finished the 1570 miles of travel over American roads, which were in many places truly horrible for days together, with all their springs in as good condition as when they started, but many other contestants reached Jersey City July 24 with one or more springs out of work, blocked up, thus throwing all the load on the tires.

Some of the Glidden Tour cars, not very many, however, started out with various forms of spring checks or supplementary spring devices, some of which failed completely early in the Tour, and none of which, so far as continued observation thruout the tour could determine, did what was hoped for at the start.

Most of the Glidden cars were on half-elliptics, but some of them had full elliptics, and all of the full elliptics did very well indeed.

The half-elliptic spring gives advantages in the way of construction and car-body support which cause them to be preferred by a very large majority of car designers, but even the full elliptic spring, which is twice as quick in movement as a half-elliptic of the same length, is too slow to give ideal car-body support.

The ideal car spring would rise so rapidly that the dropping of a wheel into a road surface depression would not cause the car-body to drop at all until the depth of the road depression exceeded the range of the spring, and would also yield so promptly that no road obstruction not higher than the range of the spring, would lift the car-body. But no springmaker has yet shown springs that moved quickly enough to produce these ideal conditions. Since the full elliptic is twice as fast as the half-elliptic it is very clear that if rapidity of spring movement is what is needed, then the full elliptic is vastly preferable to the half-elliptic.

Another condition very greatly in favor of the full elliptic, is the fact that for a given range the full-elliptic springs have only half the spring-member travel, at the free ends, which the half-elliptics must make. If a half-elliptic spring has, say, 4 inches working range, then the top spring leaf must bend 4 inches to cover the range. But a full elliptic spring to give 4 inches' range, has to bend its long members only 2 inches each, to give a 4-inch total rise and fall, so that the full-elliptic spring is not only twice as quick as the half-elliptic spring, but has to bend only half as much to give equal range.

Now it is well known that any spring, even if made of soft iron, will bend a little way without hurting it at all. The most durable spring known to lockmakers is the old German coil of many turns of soft hammered iron, not steel at all, wound round the piece to be moved. Such lock springs would give, say, a quarter turn of a lock-handle and return it, forever, without change, if kept from rusting. Hence it appears that the length of spring travel has great influence on spring durability, as is, indeed, perfectly well known to be the fact, and this makes it possible for a full elliptic spring to give, say, 4 inches' range without harm, even tho made of very common material with little attention paid to tempering, while a half-elliptic to give 4 inches' range, and stand, would need to be made of costly special steel, and be tempered with the greatest care.

Many of the Glidden Tour half-elliptics were made of selected steel, and were carefully tempered, and went thru in good shape, ending in perfect condition.

But full elliptics, costing much less, did the same thing, and as the full-elliptic spring can be so applied to a car as to give satisfactory body support, as was shown in the Glidden Tour, it seems that the full-elliptic spring should have very careful and full consideration from motor car designers before the costly, special-steel, graded and tempered half-elliptic spring is accepted as the only first-class practice.

The 2-Cycle Car Motor

The story in a recent issue of the Journal concerning the performance of the Reliance four-cylinder, two-cycle motor proves beyond question that the two-cycle motor is in every way perfectly suitable for motor car driving. In this very hard run of 144 miles the motor was always powerful, had no "muffler explosions," that is to say, passed no unfired charges from the cylinder to the muffler, and was extremely flexible, varying the pace of the car by throttling from about seven miles on high gear, which is only 2 to 1, to 60 miles. The four two-cycle cylinders give the same number of impulses to the crank-shaft per revolution that would be given by an eight-cylinder four-cycle motor. The Reliance trucks are showing the best of work with two two-cycle cylinders, which give the same crank-shaft impulses as a four-cylinder four-cycle motor.

Hosted by Google

The story given of the Adrian two-cycle air-cooled motors shows conclusively that the two-cycle motor is much more easily cooled than the four-cycle motor.

The Gulick two-cylinder two-cycle motor in the American Simplex car, Mishawaka, Indiana, also shows exceptional motor performance. In addition to these three stories of two-cycle motor work in car driving there is also the work of the Elmore cars, which have been in use for some years, and are well known to be economical of fuel.

In view of these successes it is somewhat surprising that more of the manufacturers have not yet taken up the development of suitable two-cycle engines for their cars. This may and doubtless is largely due to the fact that the buying public are not yet educated to the point of demanding two instead of four-cycle engines. However, when the time comes, doubtless the motor-car makers will give them what they want.

Meantime, the best that can be done is to fairly and fully record the successes of the two-cycle motor, both water and air-cooled.

The Multiple Stand Pipe Carburetor

No man can make a carburetor that is absolutely right, as is clearly proved by the constant changes in this wholly needless gas-engine despair. The only right thing to do, in the writer's opinion, is to throw away all the present vaporizing practice and use measuring pumps that will deal with the fluid fuel, measuring a variable quantity of the liquid to each cylinder for each cylinder charge. Some of the mechanical oilers will answer perfectly as fuel pumps, and one manufacturer told the writer he would soon apply his oiler to fuel feeding. As is clearly shown by the practice of some motor builders who employ flooded oiling systems, the precision oilers, with all their complications, are needless. "Ridiculous," to quote Mr. Ferguson, designer of the Pierce Great Arrow, but while they are not the thing for oilers, they have been developed to great certainty of action in measuring minute variable portions of fluid, and are all ready to apply to motors as fuel feeders. The fuel feed by pump is broadly covered by an expired English patent to Griffiths, who informed the writer that while the pump fuel feed worked all right the vaporizing carburetor was simple and cheap and he regarded the vaporizing system as the right thing. But it is now painfully evident that no one vaporizing carburetor is just right because every motor maker has one better than any other fellow's. There are too many variables in the vaporizing carburetor problem, and one of these variables, the condition of the atmosphere as to temperature and humidity, which makes a lot of difference in carburetor action, cannot be controlled by any man. The right thing to do is to suck air with the motor piston and inject fluid fuel into this air as the air goes into the cylinder. Then the air intake can be free for the maximum charge, instead of having to be always somewhat throttled, as it must be with the vaporizing carburetor.

But the vaporizing carburetor will be used for some time yet, and it is of interest to know its best form.

If the delivery nozzle of the carburetor stand pipe, and the area of the air-intake surrounding the gasoline delivery stand pipe nozzle could be regulated to suit the motor requirements of the instant, the action would be better. Several makers, as Menges and Matheson, use three stand pipes, each giving a different volume of fuel, and Schebler has just now put out a carburetor with two stand pipes. Various attempts have been made in the direction of needle-valve, stand-pipe delivery regulation and expanding and contracting air intake passages, but these variable elements involve delicate complications which have told against them, so that two or three different stand pipes, each with its own different diameter air intake appeals just now to a good many motor makers.

There is nothing complicated about the duplicate or triplicate stand pipe, and it is easy to make the motor use the most suitable one. The ground work of the multiple stand pipe carburetor is old, so that the field is broadly free, and only construction details can be covered by patent.

The triple stand pipe works to admiration with the Menges motor, which has a very flexible control, and the first and only 2-stand pipe Schebler carburetor is said to be showing very well indeed; perhaps there are now other American examples of the multiple carburetor stand pipe, originally a French conception, and this carburetor modification seems likely to be largely used, altho it is only a make-shift at best, and does not go to the root of the evil.

Undoubtedly the use of gasoline for motor car motor fuel will be abandoned in favor of heavier oil, which does not vaporize very easily, and this will require fuel feeding in liquid form, by pumps or by a variable admission of some sort.

It should be borne in mind that perfect combustion produces an odorless exhaust, and that the car which leaves an odor behind it is certainly wasting fuel, which makes it clear enough that there is yet some work to be done by car motor designers.

The suppression of the Stuttgart international race is regarded as the first step by the German government toward the complete prohibition of automobile racing on the highways of the empire, in accordance with the wishes of the Minister of the Interior.

Not the least of the good points gained by having the Automobile Shows come early is that the manufacturers have been forced to start in earlier on their 1908 models. Many prominent companies have already their 1908 models for sale.

Hosted by Google

The Friction Drive

The friction drive is now a pronounced success, the Cartercar and the Lambert and Levigne's "Griswold" using aluminum discs and paper wheels with satisfaction, while the Rochester "Gearless" with fibre beveled pinions, and the Meiselbach trucks, with beveled pinions of tar-paper, drive perfectly. The Cartercar, Lambert, Gearless and Griswold are passenger vehicles, the Lambert and Cartercar both having offered trucks and delivery wagons, while Meiselbach is making commercial wagons only.

Lambert and the Cartercar and the Griswold use aluminum and straw-board coacting surfaces, and use driving discs and traversing pinions or "paper wheels," regular disc and pinion drive form, the novel features being found in the materials, aluminum alloy for the disc face and fibre in some form, vulcanized fibre, straw-board and tar-paper being used for the pinion face.

The Gearless and Meiselbach use beveled pinions coacting with beveled surfaces of grey iron. These beveled friction drives are generally of one speed only. The Gearless obtains two speeds by an epicyclic action, using the same bevel pinions and coacting beveled wheels for both high and low gear. Meiselbach, after many failures and spending much time and money, produced a two speeds forward and reverse drive with three sliding bevel pinions and a pair of opposed, grey iron, bevel friction wheels, having each a large and small beveled driving surface, and obtaining the low speed or the reverse by sliding a front or rear bevel pinion into contact with the larger diameter beveled driving surfaces, and the high forward speed by forcing an intermediate bevel pinion into surface engagement with the smaller diameter beveled faces of the two grey iron driven wheels. Meiselbach has now discarded the intermediate pinion and the smaller driven wheel surfaces, and has a one forward speed drive with one speed reverse, and is the only user of friction driving within the writer's knowledge to wholly omit the balance gear, and depend entirely upon the slipping of friction on the slow side on curves to equalize his driving wheel movement.

Brush, in his 1907 runabout, employs a form of friction drive, all steel surfaces, in which variable speeds forward are obtained with a direct drive on high speed with no use of friction adhesion, the driving shaft and driven shaft having the same axis on high gear. The Brush drive is so very different from the others named here as to be in a class by itself, but is like the Meiselbach drive in discarding the balance gear, tho unlike the Meiselbach, in that Brush disengages his slow wheel and drives with the outside wheel only on curves, while the Meiselbach truck drives both wheels on curves, slipping the friction engagement on the slow inside driving-wheel side.

Meiselbach boldly discards both the speed change gear and the balance, or "compensating," gear, and the writer is able to assert from his own observation that the fully loaded truck drives perfectly on short turns, with no hint whatever of any need for the omitted balance gear. The speed change gear omission is not noticed in the road work of the car, as the throttle gives a good range of speeds. The ordinary pace of the truck is about six miles an hour, much more than twice the walking speed of horse teams.

The writer fully believes that friction drive is in every way as effective and as suitable for motor cars of all kinds as any form of toothed gearing, and if a loaded truck having no balance gear makes short turns strongly on poor roads, it fully proves that the balance gear is not needed.

If the gas-engine car-motor has piston area enough to give a strong drive at slow speed, so as to take the car over muddy and sandy roads and up hills, then one forward speed is enough. Increase of piston area entails but little increase of gas-engine weight or cost.

The performance of these friction driven vehicles gives good support to the contention that the speed-change gears and balance gears are not needed for successful motor car driving, and if this is true motor-car builders cannot be made aware of the facts too soon.

Length of Wheel-Base

The large number of low priced "high-wheel" cars which are just now being brought out have very short wheel-bases. Is the short wheel-base right for any car, no matter what the price, or does it constitute a serious error in design?

The first cars had short wheel-bases, some as low as 58 inches, and the wheel-base was steadily increased, and is now from 100 to 128 inches for cars which claim good design.

It is perfectly well understood by car designers generally that the longer the wheel-base the better the car rides, and that 100 inches is as little wheel-base as a car should have if the comfort of passengers is to be considered; yet the designers and builders of the buggy type of cars are going back to the old figures of 68, 70 and 78 inches wheel-base, and are preparing to flood the market with low cost cars which are too short in the wheel-base to give the best results on the road.

It seems that the high-wheel designers have resolved to go back to horse-drawn "buggy" lengths, because horse drivers are accustomed to the short wheel-base, and are therefore more likely to buy cars

Hosted by Google

which have the wheels closer together than those of 100 inches or so wheel-base. The designers are probably also influenced by the fact that a short-wheel base car costs a little less than a longer wheel-base, and the buggy-cars must be as low priced as possible.

The fact is that the horse-drawn buggy wheel-base, or length of road support, really includes the length of the horse as well as the distance between the buggy wheels, so far as stability is concerned, and that the horse-drawn buggy base is, in fact, more than 100 inches, which the majority of car designers consider a motor car must have to carry its passengers in comfort on rough roads.

The horse acts as a support so that a buggy cannot be overturned while the horse is on his feet unless something breaks. This makes the short wheel-base buggy pretty safe against overturning. But when the horse is taken away the short high-wheel car has no such support, and is more liable to capsize.

The buggy car builders want to make their cars turn in a small space, and so assume about 78 inches as the extreme limit of road base. A 100-inch wheel-base car is not so long or does not take up so much street room as a horse and buggy taken together, and can turn in almost as short a space.

As to cost the 100-inch wheel-base car costs very little more than the 78-inch wheel-base car. It is the two ends of a wheeled vehicle that cost, and the buggy car can be stretched in the middle for very little money.

When it comes to riding on a bumpy road, every added inch of wheel-base adds to the comfort and security of the passengers. The short wheel-base buggy-cars are very uneasy things when driven over ten miles an hour, which is about as fast as a horse and buggy can average. But even a farmer will not be contented with a ten-mile high-wheeled pace, which seems like crawling in a motor car.

Taken altogether it seems pretty certain that the short wheel-base is an even greater mistake in the high-wheel cars than in the 28 or 30 inch wheeled motor car, where the wheels are so low as to greatly reduce the chances of upsetting, and that the high-wheelers, should they come into vogue as expected, will have the wheel-base increased regularly as did the early motor cars, because the greater length increases the cost but very little, yet adds greatly to the comfort and safety of the passengers.

A cigarette dropt into a gasoline tank in the Howard Automobile Company's garage at 408 Golden Gate avenue, San Francisco, caused the burning of six buildings. The damage is estimated at $60,000. The other automobile places included in the fire are: Silent Automobile Company's garage, 404 Golden Gate avenue; Boyer's Automobile headquarters, and the automobile supply establishment belonging to Hughson & Merton.

President W. H. Hotchkiss and Charles T. Terry, chairman of the Legislative Board of the American Automobile Association, are both members of the Congress on Uniform Laws, composed of delegates appointed by the Governors of different States. This Congress will take up the subject of a uniform automobile law and present for adoption by the Legislatures of the different States a model bill drawn by Charles T. Terry.

One of the features of the Madison Square Garden show this year that will attract the attention of the followers of bicycles will be the first complete exhibition of motorcycles ever held in this country. Thirty-one manufacturers of motorcycles have been allotted space.

The annual automobile show luncheon of the American Motor Car Manufacturers' Association will be given at the Manhattan Hotel on Tuesday, October 29 of the week of the automobile show at the Grand Central Palace, New York.

Hill-climbing contests with cars especially geared for the purpose are of little practical value to the man who wants to know what the car that he buys will do on a hill. Every one who has had any experience knows that it is possible to gear a car up so that it especially suits some particular hill, and also that the same car on another hill where the grade varies may "fall down" badly.

The test of the all round utility of a car is to get it out on the country roads with its full complement of passengers.

A complete list of automobile licenses in the United States, compiled from official records to June 15, shows a total of 203,630. New York heads the list, with New Jersey, Massachusetts, Texas, Pennsylvania and Illinois following in that order.

The Government in India is considering the desirability of using motor-transport wagons for freight in moving produce of out-of-the-way districts to market. This is entirely practicable, considering the good roads to the plains in India, and it would solve a perplexing Government problem.

The Glide Automobile Club has been formed in Peoria, Ill., with a membership of twenty-seven. The club is composed entirely of owners and users of the Glide cars.

The Ideal Carburetor

By E. W. Roberts, M. E.

As at present made the carburetor or mixing device for a gasoline engine, especially if employed for automobile purposes, must be so designed that it gives a practically constant mixture at all speeds of the engine. In order to draw the gasoline into the air passage while the engine is on the way, a vacuum must be produced around the nozzle leading to the float chamber in order to draw gasoline into the air stream. The amount of vacuum required to draw in the proper amount of gasoline depends on the size of the gasoline passage thru the nozzle and must be greater, as the size of the passage is smaller. With a given opening of the air passage around the gasoline nozzle, or, as is it is usually called, the "strangle tube," the vacuum increases with the speed of the air passage thru it. With a given size of gasoline passage, the quantity of gasoline drawn thru, increases faster than the volume of air going thru the strangle tube. Hence at high speeds and a consequently higher velocity of air current, the amount of gasoline is so much greater in proportion to the air that the mixture is increased in richness; that is, it has a greater proportion of gasoline. Hence with the average carburetor if the area of the strangle tube is constant at all speeds of the engine and no provision is made for compensation, the constant mixture cannot be obtained.

The greater number of carburetors compensate for this peculiarity by means of an auxiliary air passage admitting air into the mixture in such a way that it does not pass thru the strangle tube, in other carburetors, the area of the strangle tube, or what amounts to the same thing, the vacuum surrounding the gasoline nozzle, is so regulated that it is just sufficient to draw in the right amount of gasoline at all speeds. In both these types of carburetor this is accomplished by a spring-controlled valve, the valve being opened by the suction of the ingoing air current as the speed of the engine increases. In order to accomplish this, however, it is necessary to put a certain drag on the inlet air and consequently at high speeds the engine does not get so nearly a cylinder full of air as it does at lower speeds. It practically amounts to the same thing as a partial closure of the throttle.

It is an old trick among motor boat operators to hold this valve wide open when racing. To compensate for taking the drag off the air current, which would weaken the mixture, the needle valve is given a slightly increased opening. Another way in which this is accomplished is to use a manually-operated valve of the same size as the compensating valve which is opened when racing and when this is used the needle valve must be opened wider.

The ideal carburetor so far as compensation is concerned would be one in which there is no drag at any speed of the engine. This is accomplished in a way by certain types of carburetor in which the compensation is obtained thru the throttle valve. In other words, the compensation is manual rather than automatic. Carburetors of this kind, however, do not as a rule respond as promptly to the throttle and, in handling an engine with such a carburetor, the throttle must be opened gradually or the engine is very likely to stop when its power is most needed. Then there are troubles with the float valves, floats and all the mechanism of the float-chamber. These, however, have been to a great extent overcome in the latest improved carburetors, but they still remain to a greater or less extent.

The float that is quite universally used is cork, usually varnished with shellac because shellac is insoluble in gasoline. Corks that are not varnished are apt to gradually absorb gasoline into their pores. With the advent of alcohol shellac can no longer be used for this purpose, as alcohol is the solvent of shellac. Faults of float chamber mechanisms are principally floats with valves that stick, float valves that leak or are easily unseated by the jar of the automobile. It is most annoying to have a float valve that will act beautifully as long as the automobile is standing still, but just as soon as the machine is run, allows the carburetor to flood. Then again there is the float valve that will stick and yet when the automobile stands still will work perfectly, but a sudden jar on the road will make the valve jump off its seat and remain there, or will not leave its seat and allow the float chamber to become dry. But it is quite probable that with the advent of alcohol the cork float will have to be abandoned and the metal float used instead.

The great trouble with the metal float is its liability to leak and thereby lose its efficiency. This trouble is not lessened by the fact that a leak in a metal float is very difficult to find, especially if it is a very small leak. True, there are carburetors made without float chambers, but so far they have not proved popular, for, as a rule, the remedy is worse than the disease. The ideal float chamber mechanism is one that will shut the gasoline off under a wide variation of pressures, owing to the fact that quite a number of automobiles have their gasoline supplied to the carburetor by air pressure, and a valve that will open promptly with a very slight variation of the level. There are other faults in float chamber mechanism which are not worth mentioning, as they are practically all overcome in the modern carburetor.

Motor and Accessories Manufacturers held their semi-annual meeting at Atlantic City, N. J., August 8-10, in the Shelburne Hotel. No publicity has been given as to what transpired, but it is understood that much of the time was occupied in considering and adopting the new charter lately granted by the Connecticut legislature, and the new constitution made necessary by the revised charter. About 70 members were present.

Fires, Judgements and Failures

Aerocar Company, of Detroit, Mich., in receivers' hands. Creditors met and appointed Detroit Trust Company trustee in bankruptcy. Receivers' inventory shows assets as $189,243. Liabilities amount to $300,000. Creditors appointed a committee to confer with trustee as to the advisability of continuing the business.

American Roller Bearing Company, South Framingham, Mass.; receiver Frederick B. Hill, of Framingham, Mass., was appointed upon a petition filed by Hyatt Roller Bearing Company, of Newark, N. J.

Boyd automobile store, 419 Massachusetts avenue, Indianapolis, Ind., was damaged by fire to the extent of $500, August 29.

Croft Brothers garage, 51-55 Evanston avenue, Chicago, Ill., damaged by fire to the extent of $100,000. Insured.

Cantono Electric Tractor Company, of New York, has been petitioned in bankruptcy.

Detroit Auto Vehicle Company, of Detroit, petitioned by creditors for the appointment of a receiver July 11, is not bankrupt, and the company's attorneys will contest the apppointment of a receiver before a jury.

Deere-Clark Motor Car Company, Moline, Ill., has been petitioned in bankruptcy by four creditors.

Eastern Battery Company, 42 Thurston street, Pawtucket, R. I., damaged slightly by fire.

Grout Brothers Automobile Company, Orange, Mass., plant is to be sold to satisfy the claim of W. L. Grout, who petitioned it into bankruptcy.

Holmes Motor Vehicle Company, East Boston, Mass., has been petitioned in bankruptcy; $571 aggregate claims of creditors.

Howard Automobile Company, 408 Golden Gate avenue, San Francisco, Cal., August 25, damaged by fire.

Hughson & Merton, located in Larkin street, San Francisco, Cal., auto supply business, destroyed by fire.

Huber Automobile Company, Detroit, Mich., has filed a petition in bankruptcy.

Knox Motor Truck Company, of Springfield, Mass., makers of the Atlas truck, has been enjoined by court from using the word Knox in connection with its business, and will change the style of the corporation to Atlas Motor Car Company.

Marvel Motor Car Company, of Detroit, has been petitioned by creditors, asking that the company be adjudged bankrupt.

Pope Manufacturing Company, of Hartford, Conn., hearing on the receivership which was set for September 16, was held before Judge Case, of the Superior Court in Hartford. A. L. Pope, the receiver, was present, as was also his attorney, Arthur L. Shipman. Several creditors were represented by their lawyers, but none of those who had attended the August hearing. An inventory was filed, and a more extended inventory will be filed October 16. No opposition developed to the appointment of A. L. Pope as permanent receiver.

Pennsylvania Rubber Company, of Jeannette, Pa., defendant in the suit of the G & J Tire Company, claiming infringement of patents, has been released. Judge Buffington, sitting in United States Circuit Court for Western District of Pennsylvania, handed down his decision, in which he claims that no infringements of any of the patents is shown; the bill will be dismissed on presentation of a decree.

Reliable Automobile Company, Tacoma, Wash., has made an assignment to George Wotten for the benefit of its creditors. Liabilities, $21 670; assets, $6,050.

Robinson, Birney A., Worcester, Mass., dealer, filed a voluntary petition in bankruptcy. Liabilities, $20,939; assets estimated at $9,300, of which $4,000 is represented by book accounts.

St. Clair Motor Company, Detroit, Mich., on August 22 was petitioned in bankruptcy by three creditors.

Snutsel, Inc., Paul N., wholesale dealer in auto supplies, 1535 Broadway, New York, has been petitioned in bankruptcy.

Silent Northern Automobile Company's headquarters, 404 Golden Gate avenue, San Francisco, Cal., damaged by fire August 25.

St. Louis Car Company, manufacturer of the American Mors, will reorganize, President Kobusch having succeeded, it is stated, in securing financial support from St. Louis residents. The automobile department will be separated from the street car end entirely, and the reorganization will be followed by additions to the equipment and enlargement of the plant. Notice of the increase of capital stock from $3,000,000 to $6,000,000 has been filed.

Trade Changes and Removals

Angier Auto Supply, 222 Park Square, Motor Mart, has been succeeded by the Butler Auto Supply Company, Mr. H. M. Butler having purchased the interest of O. M. Angier.

Boston Auto Gage Company has removed its headquarters from 614 Old South Building to 8 Waltham street, Boston, Mass.

Brooklyn Motor Car Company, of Brooklyn, has reincorporated as the R. E. P. Sporting Goods Company, and will be located as heretofore at 1384-1386 Bedford avenue.

Cleveland Motor Car Company, of Cleveland, inform us that after October 1 the headquarters will be in New York City, with offices at 1659 Broadway.

Dragon Automobile Company, of Philadelphia, recently reorganized with the following officers: President, John Kane Mills; vice-president and treasurer, Henry Rawle; second vice-president and sales manager, A. L. Kull; general manager, J. H. O'Brien; directors, J. F. Grimes, Pittsburg; John Kane Mills, New York; Henry Rawle, Philadelphia; A. L. Kull, New York.

Harrolds Motor Car Company, New York agent for the Pierce cars, has removed from its old location at Broadway and Fifty-ninth streets to 233 West Fifty-fourth street.

Hartford Automobile Parts Company, of Hartford, Conn., has filed a certificate of an increase of $6000 in its capital stock, making the total amount of capital stock $10,000.

Knox Motor Truck Company, of Springfield, Mass., enjoined from using the word Knox in connection with its business, will change to the Atlas Motor Car Company.

Manhattan Storage Company has changed its headquarters from 42 Cortlandt street, New York, to 1611 Broadway. The store at 42 Cortlandt street being discontinued.

Menges Motor Car Company has removed its plant from 14-18 Mill street, Grand Rapids, Mich., to Elkhart, Ind.

Reo Motor Car Company, of Lansing, Mich., has declared a stock dividend of 33 1-3 per cent., and its stockholders voted to increase the capital stock from $750,000 to $1,000,000.

Snow, C. D., informs us that he is no longer connected with the C. D. Snow Company, having formed the Snow Automobile Company with offices at 86 Dorrance street, Providence, R. I. They handle the Stevens-Duryea cars for Rhode Island and Attleboro.

Legislative and Legal

MASSACHUSETTS.

Pittsfield.—Ordinance regulating the speed of automobiles and motorcycles has been passed increasing speed to fifteen miles per hour.

NEW JERSEY.

East Orange.—A special ordinance for the guidance of public and private garage owners and operators was presented. The bill provides that in the future a license of $10 will be charged an owner of a public garage, and $1 for a private one. No gas or lamp lights are to be used; all lights on the autos are to be extinguished before entering the garage; no smoking is to be allowed, and signs are to be prominently posted to that effect. Sand is to be kept in buckets ready to be placed on oil that may drip on the floor. The penalty for violation of these rules will be $10.

A decision lately given for $101,789.10 against the New York Central Railroad in the Supreme Court before Justice O'Gormon for the death of Frank B. Read, in favor of his wife, for damages, failed to draw as much attention as it should have done. Mr. Read was killed at the railroad crossing at Van Cortland Park while traveling in an automobile. The automobile was struck by an engine concealed by the surroundings. Others in the accident were given big damages. A few more expensive accidents of the same nature might result in over or under crossings and save many a life.

Aluminum Alloys

Rochester, N. Y., September 14, 1907.

We have noticed and read with interest the various articles which have been published in your last three or four issues on the subject of aluminum castings, in which is taken up a discussion as to the relative merits of alloys of zinc aluminum and alloys of copper aluminum. We have also been amused to see how sharply the lines are drawn between the two classes of alloys, and how strongly their respective champions stand for their own preference as the best metal for all purposes.

We have been 25 years at the brass foundry business, and years ago, when aluminum was first introduced, and before the automobile business came into existence as a commercial factor, did a great deal of experimenting with aluminum alloys. Our Mr. Clum, together with the manager of the Cowles Electric Smelting and Aluminum Co., made numerous experiments to determine the best alloys for various purposes, and some 15 years ago we were making in our own foundry aluminum castings for special work, which our Lockport friends had been unable to have made successfully elsewhere.

In connection with the Eastman Kodak Co., of this city, we have been called upon to do considerable experimental work in adapting aluminum alloys to their special machinery and chemical processes.

Going through all the ins and outs of the aluminum casting proposition, as practical founders, from its early history up to the present time, we have found not one or two, but many useful alloys. In our brass and bronze business we are accustomed, as are others, to a wide range of mixtures for as wide a range of uses. Users of steel are familiar with the fact that a steel suitable for one purpose may be totally unfit for another purpose, although it may be of as high a grade as the steel that is capable of doing the work. So in aluminum alloys the use to which the casting is to be put should determine the alloy. Zinc aluminum is superior to copper aluminum for some purposes, while for other castings the conditions may be such that the copper aluminum is so much better than a mixture with zinc in it that it is almost imperative that the copper alloy be used.

With one of our customers, the Mora Motor Car Co., of Newark, N. Y., we have recently been through a series of experiments for their 1908 car, and this company will use three separate and distinct mixtures of aluminum on their car.

We frequently see published reports of physical tests made of test bars showing wonderful, even impossible, combinations of good qualities. While scientific tests are necessary aids and are all right in their place, there are some things for the manufacturer to bear in mind as he reads them. Test bar records are like track or road records. A half dozen or more of well tuned cars may be entered, and if one makes a creditable performance, that is the one talked about. The same with test bars: "Many are called, but few are chosen." Moreover, every practical foundryman knows how to obtain quite a variety of high or low tensile strengths, elastic limits, and the rest at will, and all out of the same pot of metal, by a little manipulation in the making of the test bar. The making of the casting is a separate proposition, and the best test of the casting is the test of actual service.

With the introduction of the motor car industry, and the foundries that have sprung up in its wake, it is natural that aluminum alloys should again be put through the experimental stage, and while the subject is new in the minds of so many, that there should be a good deal of more or less heated discussion on it; yet we believe the manufacturers are inclined more and more to pay less attention to technical discussion and trust rather to their business ability in selecting a practical foundryman, and trusting to him to furnish castings suitable for the work to be required of them, and which will stand up under the test of actual service. CLUM & ATKINSON.

Albert L. Pope's Resignation Refused

At the monthly meeting of the executive committee of the National Association of Automobile Manufacturers, held September 4, in the association's New York offices, the only matter outside of the usual routine was the resignation of Albert L. Pope as president. The executive committee unanimously refused to accept his resignation, and the secretary was instructed to wire Mr. Pope of their decision.

Other business transacted was that of accepting the resignation of G. W. Bennett, caused by the change recently made by him from the Knox Company to the White, and the filling of that vacancy by M. L. Goss, Baker Motor Vehicle Co.

Doing the Right Thing by Autoists

The Middleboro, Mass., authorities, in conjunction with the Middleboro Automobile Club, have taken unique steps to warn automobilists of the speed laws in that town.

The club has placed large canvas banners across every street leading from the outskirts to the thickly settled districts, bearing the name of the town, speed limit and an appeal for a square deal. The banners read as follows: "Middleboro, 12 miles per hour thru town. We give you a square deal. Give us one. Middleboro Automobile Club."

New's Gold Medal Awarded for Climb of Giants' Despair

The Wilkes-Barre Automobile Club members who acted as judges and referee of the last hill climbing contest up Giants' Despair, Wilkes-Barre, Pa., have announced the results of the competition for the "New's" Gold Medal, which was to be awarded to the car drawing the greatest weight per horse power per second. The Matheson car, driven by Ross Anderson, proved to be the winner.

The weight drawn by each contestant per horse power per second was arrived at as follows: The cars were weighed and their horse power determined by the formula recently adopted by the Association of Licensed Automobile Manufacturers. With these figures the weight drawn per horse power was determined. Then by taking the fastest time made by each contestant in the climb the weight drawn per horse power per second was obtained. The following table gives the results of the first six cars:

Car.	Driver.	H. P. lbs. per sec.
Matheson	Ross Anderson	.5535
Fiat	Kessler	.4984
Matheson	Charles Ward	.4118
Knox	Bourque	.4063
Thomas Flyer	M. Roberts	.3649
Maxwell	Price	.3268

Morris Park 24-Hour Race

At 11.55 P. M., Saturday, September 7, the 24-hour race at Morris Park, New York came to an end, with the 35-45 horse power Renault car as victor. The car was driven alternately by Maurice Bernin, and Carl La Trois, and covered 1,078 miles, beating the record of the Thomas car at Brighton Beach by 81 miles. Nine cars started in the event. The A-K car made an excellent showing for a new car, as this was its first actual appearance on either the track or road. During the intermission on Saturday another car backed into it, puncturing the radiator which caused a delay. This, however, was the subject of an allowance by the referee. Final score:

Renault	1,078
Lozier	972
Hotchkiss	892
Allen-Kingston	681

Only One Clean Score in Cleveland Run

The only contestant in the three days' sealed bonnet contest of the Cleveland Automobile Club, September 10, 11, 12, to survive with a perfect score was, a four-cylinder Gaeth car driven by Paul Gaeth. The Mora car made the next best showing, it being only penalized 25 points for the stopping of the motor. This was an accidental stop caused by a broken tire chain catching in the brake. A four-cylinder Buick was next, it being penalized 40 points for the taking on of water, which was necessitated by a leaky radiator caused by the carelessness of a driver at the garage. These three cars all finished with intact seals. The test was run over the roads around Cleveland, the most of the time in a downpour of rain. The distance traveled the first day was 138 miles, second day 152, and third day 156 miles. Daily penalizations:

Car.	Driver.	First Day.	Second Day.	Third Day.	Total.
Gaeth,	Paul Gaeth	0	0	0	0
Mora,	J. W. David	25	0	0	25
Buick,	H. J. Trumball	0	0	40	40
Cartercar,	B J. Carter	120	135	255	549
Cartercar,	A. W. Hall	562	134	75	771
Buick.	George Bettes	551	0	Broken chain.	
Jackson,	R. Burman	Tire trouble, abandoned.			
Jackson,	C. D. Paxon	Seized bearing, abandoned.			

Wildwood's Auto Carnival

On Monday, September 2nd, sixteen cars started from Gloucester on a regularity run to Wildwood, N. J., to take part in various events scheduled for the remainder of the week. Of the sixteen starters, eleven finished with scores next to perfect, altho not one absolutely perfect score was registered. The first prize awarded for this run was captured by Ira L. Brown, driving a Pullman. The six days sealed bonnet endurance run was called off on account of an insufficient number of entries. The most notable event of the week was a mile made in 43 seconds by Bert Holland in a Stanley steamer, on Thursday, thereby breaking the record by one second, made by Montague Robert on July 4th over the same course. Under the condition that no entrance fee was charged for any of the events, it was surprising to note the scarcity of cars. Besides the touring car records good showings were also made in the runabout class.

Early Date for Quaker City Show

Announcement has been made by the Philadelphia Automobile Trade Association that it will hold Philadelphia's annual automobile show this year November 9 to 16, following that of Madison Square Garden, New York. President Smith appointed the following: George H. Smith, White Steamer; Edward Leeds, of Titman, Leeds & Co., E. H. Fitch, of Diamond Rubber Co., and Fred Vanderhoff, of the Ford Co., as a show committee. J. H. Beck has been engaged as secretary. The place for holding the show has not been decided upon as yet.

The proposed hill climb of the Automobile Club of Bridgeport, Conn., scheduled for Labor Day, has been postponed until Decoration Day, May 30, 1908.

The consensus of opinion seems to be that the gradual increasing of wheel bases has reached its limit, and that 1908 will not see cars having a much longer wheel base than 1907. A few of the 6-cylinder cars may prove the exception.

Hosted by Google

Proposed Stock Car Race For Long Island Discarded.

There will be no stock touring car race over the Vanderbilt Cup Course this season. The proposed plan of the Metropolitan Automobile Association to hold a stock touring car race on Long Island, October 16 and 17, came to a sad ending on September 9, when the formal application for the use of the highways was withdrawn. This decision was reached by the association on its appearance before the Board of Supervisors, on account of the hostile influences that had evidently been brought to bear on the authorities.

Recommendations for 24 Hour-Contests.

The following announcement was recently made by Secretary Elliott, of the American Automobile Association:

The racing board of the American Automobile Association has received from its technical advisers the following recommendations respecting the entries of cars in twenty-four-hour endurance contests or relay races, and requests that the promoters of such contests provide each entrant with a copy of these recommendations, believing that by complying with the same the safety of the contestants as well as the spectators will be better safeguarded, and accidents similar to those in former contests will be eliminated as far as possible:

First—That the tail lamps on each car shall be illuminated either by acetylene gas or electric lights supplied from accumulators, and that no car should be permitted to start which is equipt with tail lights using kerosene.

Second—That all entrants and drivers ascertain that their tire lugs are of the proper size for the tires, and it is not thought advisable that any car should start which does not use at least six lugs for each tire. This suggestion applies only to cars equipt with clincher tires.

Auto Parade Feature of Old Home Week.

As one of the many excellent features of Buffalo's Old Home Week celebrations, the Buffalo Automobile Club promoted an automobile parade on Tuesday evening, September 3, in which over two hundred and fifty gaily decorated cars participated. The Thomas car of E. R. Thomas won first prize. The design of decorations was an eagle's aerie. The machine was covered with an abundance of streamers and flowers, and resting above the tonneau was a large eagle with outstretched wings protecting the nest.

Date For St. Louis Balloon Race Changed.

The date for the Gordon-Bennett international balloon race set for Saturday, October 19, has been changed to Monday, October 21. This announcement was received by cable from Courtlandt F. Bishop, now in Paris.

Crude Para Rubber has been reduced by the United States Rubber Company and the independent dealers from $1.06 to $1.05 per pound, the lowest figure reached for three years.

Exports Still Increasing.

The exports for July show a growing increase. July, 1907, the exports reached a total of $796,325, a gain on June of 1907 of $64,271, and an increase of $283,146 over that of July, 1906.

Exported to	July 1906	1907
United Kingdom	187,909	301,126
France	71,046	121,627

Other countries	.....	618
Total auto and parts	$513,179	$796,325

The following communication was received by the "Cycle and Automobile Trade Journal," and is herewith published, as the individual referred to may endeavor to swindle other members of the trade.

Plainfield, N. J., September 17, 1907.

Cycle Automobile and Trade Journal,
Philadelphia, Pa.

Gentlemen:

We had a call the other day from a very slick individual with a strong English accent, who claimed to be H. G. Graham, son of the president of Argyll Motors, Ltd., Glasgow, Scotland. He claimed to have charge of the Argyll London branch, which is near our London office, seemed to be intimately acquainted with our London representatives, knew to a dollar the amount of goods we had sold in London this year, and knew that we had just received an order for a number of lights for the King's new car, and possessed a lot of other information which would make it seem certain that he was what he represented himself to be.

He stated that he had secured the contract for several thousand lights for the 1908 Argyll cars, and after showing to his own satisfaction that our success abroad was largely due to his unrewarded efforts, remembered that he was short of funds, and tried to secure a loan. Having become suspicious, we turned him over to the police, and found that he had nearly $1,000 in his pockets. As he had secured nothing from us, we let him go, but now regret this, as he appears to be a professional swindler, and he is such a slick article that we think the trade should be warned to look out for him.

He speaks very rapidly with a strong English accent, with a great deal of unnecessary profanity; is about 5 feet 5 inches, weighs about 150 pounds, has a smooth face with rather florid complexion, wears glasses, and has very poor teeth, many of them missing, as a result, he explains, of an accident when he was driving the Argyll car in the Isle of Man races last year. When he called on us he wore a blue suit and cheap plaid cap from Detroit. He showed a railway ticket on which he had just come from Pittsburg, and claimed to have just placed a $50,000 contract with the American Vanadium Co., who have just advised us that they never heard of the man.

Yours truly,
RUSHMORE DYNAMO WORKS.

At the recent outing of Massachusetts Automobile Association at Newcastle, N. H., a resolution was adopted recommending that a law be enacted to compel all vehicles to be provided with lights at night.

A. C. A.'s Eighth Annual Show, October 24-31

As usual the demand for space at the A. C. A. annual show this year was greater than the available supply, so that a remodeling of the second gallery of the Grand Central Palace, where the show will be held, was necessary. This has been done by cutting a large aisle thru the first gallery to a central stairway leading to the second gallery, and by removing the partitions in the second gallery, so that a clear space the whole width of the building (200 feet) becomes available for exhibition. This space is easily accessible.

The change necessitated the placing in the second gallery of the restaurant and cafe, which, thus enlarged, tastefully decorated and properly equipt, will adequately meet the demands of visitors and exhibitors.

The Vitagraph Theatre, where will be exhibited interesting moving pictures of famous European and American automobile races, will also be on the second gallery, on the Forty-third street side, and the exhibit of airships and balloons of the Aero Club of America will be on the same floor, on the Forty-fourth street side. It is believed that this arrangement of the restaurant, cafe, theatre, and Aero Club Show on the second gallery will make it an attractive locality alike for visitors and accessory exhibitors, to whom more than 8000 square feet of space have been assigned.

Members of the A. M. C. M. A. have been allotted 23,641 square feet of space, and members of the Motor and Accessory Manufacturers, 16,087 square feet. For the exhibition of commercial cars 4,644 square feet have been apportioned, and for motor cycles, 636 square feet. On the main floor 7,777 square feet have been apportioned for general allotment regardless of membership in organizations; on the first gallery 2,494 square feet, and in the second gallery 10,000 square feet.

There will be sixty different makes of pleasure vehicles shown and ten types of commercial motor vehicles. The members of the American Motor Car Manufacturers' Association have taken most of the space on the main floor and in the center will be found the Ford, Reo, Mitchell, Maxwell, Premier, National, Stoddard-Dayton and Wayne cars. On the Lexington avenue side the Garford, Rainier, Cleveland, Blomstrom, Moore, Frayer-Miller, Lane, Kissel, Napier, Smith and Klink models will be seen, while on the Depew place side the Crawford, Acme, B. L. M., Marion, Welch, Imperial, Cartercar, Frontenac, Gaeth, Dragon, York and Dolson cars and the Knox motor truck will be displayed. The Forty-fourth street side will be occupied by the Dorris, Gearless, Chadwick, Moon, Lambert, Moline, Marmon, Mora and Jackson cars, while on the Forty-third street side will be the Overland, American, Allen-Kingston, Evansville, Simplex, De Luxe, Glide, Pennsylvania, American Mors and Austin cars.

Tho the first gallery is to be principally occupied by the 104 members of the Motor and Accessories Association there will be a number of other cars shown there, including the Colt, Jewell, Huntington, Holsman, Schacht, Cameron, Ellsworth, Buggyabout, Reliable-Dayton and Shawmut machines.

In addition there will be a number of motorcycle exhibits and a fine showing of commercial vehicles, including the Lansden, Logan, Miller, Reliance, Mitchell, Mack, Rapid, and Frayer-Miller.

In another part of this issue of the Cycle and Automobile Trade Journal will be found in compact arrangement a group of diagrams of the floors and the space allottments of all the exhibitors from which it will be easy to locate any exhibit.

Pittsburg's Race Meet

Pittsburg's fifty-mile endurance race at Brunot's Island track, September 12, was won by William McCulla, driving a Darracq strip touring car. Time 58.40 3-5. The Darracq car was also victor in the one-mile race. The other events included an exhibition race between Barney Oldfield and Ollie Savin, the former winning; a two-mile race won by Tom Dunn, Stevens Duryea; a three-mile handicap, James Kerr Stevens winner, and an open touring car race won by Eddie Bald, with a Columbia.

Cincinnati Enjoys Racing

Barney Oldfield, driving a two-mile exhibition in 1.58 and a fast 25-mile stock touring car race, were the most important events of the two days' meetings at Latonia track, across the river from Cincinnati, on September 14 and 15. The 25-mile race was won by J. R. Rainey, driving a Stearns car, covering the course in 29.30. In all there were 19 events, ten being run on first day. Allen Ross won both motorcycle events, first day, two miles, time 3.00 2-5, and second day he rode three miles in 4.18 3-5.

The new factory of the American Simplex Motor Car Company, of Mishawaka, Ind., is now completed. The plant covers about 35,000 square feet, and will be in full operation by October 1.

The headquarters of the F. N. Motor Club of America has been changed from 2208 Broadway, to 2234 Broadway, New York City.

Automobile Dealers' Association of Baltimore, announces its show dates as the week of November 25.

Farmers are buying automobiles. Factories all over the country have been invaded lately by representatives of the farming community who have purchased cars. One sales manager of a factory in Indiana has sold a number of cars to farmers who have come to the factory to look it over. Judging from the questions asked, it is clearly shown that they have been carefully studying the question during their leisure moments.

Western Motor Company, of Logansport, Indiana, manufacturers of motors and supplies, has taken over the Rutenber carburetor, which it will manufacture hereafter.

The plan followed at the two recent 24-hour automobile races in New York of stopping the contest during the afternoon of the second day for the purpose of running off short events and watering the track has occasioned considerable criticism in certain quarters. It is thought by many that a 24-hour race should be continuous without a single intermission. A 24-hour race is mis-named if it is stopt for even a few minutes, no matter what the cause is. The fact that contestants are not allowed to work on their cars during the intermission does not alter the case. Above all things these long distance contests furnish a severe test of motors and particularly of their cooling systems. A motor which has been running hot is afforded an opportunity to cool off by these intermissions. This is not fair to those cars whose cooling systems are equal to 24 hours of continuous hard service.

Plan Submitted by Knox Creditors

About 75 per cent. of the creditors of the Knox Automobile Company, Springfield, Mass., met September 4, to form plans for the reorganization of the company.

The plan submitted provides for the issuance by the Knox Company of preferred stock to an amount not exceeding $500 000, this stock to be preferred both as to assets and to dividends, to be subject to an 8 per cent. cumulative annual dividend, the claims of creditors to include interest thereon to January 1, 1908, and the preferred stock to be of that date, all claims of $100 or in excess thereof to be entitled to one share of the preferred stock for each $100, and for each fractional part above $100 and all claims less than $100 to be paid in cash.

A statement of the inventory at the time the assignee took possession showed assets as a going concern to the amount of $970,000, and liabilities of $566,000, of which about $70,000 is preferred—$35,000 being mortgage, $30,000 money loaned by pledge of machines and balance preferred claims consisting of labor, taxes and other claims such as are preferred by the United States bankruptcy act.

A creditors' committee submitted a plan that all the creditors of over $100 be given preferred stock to the par value of their claims—said stock to be preferred as to all the assets of the company, both as to principal and dividends, if earned, to be paid at the rate of 8 per cent. per annum payable 4 per cent. semi-annually. The plan was adopted by the creditors, only two persons dissenting."

be as fully up-to-date, convenient, eedy and reliable as any cars in their ss.

The five-passenger touring car has a eel base of 112½ inches and 55-inch ge with 34 by 4 inch tires. The 4-inder 4-cycle 5x4¾ inch motor is rated 40 H. P. at 1000 r. p. m. The compres-n is 70 lbs. The tonneau doors swing the rear and the car weighs com-te 2530 lbs., and sells completely equipt dy for the road at $2750. Magneto and e top are charged for extra. The run-out seats three, but is also made to t four if desired. The chassis is the ne as that of the touring car. The weighs about 2250 lbs and completely ipt sells for $2750, the same as the ger model.

which can be squeezed together sidew so as to snap into full length chann formed in the insides of the sub-fram

It is a matter of some difficulty to vise a dust shield which will fully prot the machinery of the motor and will well retained and supported and at t same time easily removed and replac without adding more weight and c than is desirable. The method h shown, of placing fixt side-plates to co the spaces between the chassis fra and sub-frame sides, and then hangi the long trough of sheet steel by beaded edges in full length supporti channels in the insides of the sub-fra members, is very good indeed, and fu protects the under side of the Thom Detroit chassis while it is light, stro

Fig. 5. Thomas-Detroit 1908 runabout motor, right side, showing coil from exhaust pipe t ducing valve which maintains a constant pressure on the fuel tank, sufficient to ensure th w of fuel to the carburetor. In the touring car the tank is above the carburetor, and th soline tank needs no pressure. In 1907 the runabout tank pressure was had by a han erated air pump. The exhaust and reducing valve pressure is automatically maintained an eds no attention.

NOTABLE FEATURES.

The principal change is the increase of ton area. It is the rule with American s to increase the 1908 piston area, but length of stroke commonly remains same. The Detroit-Thomas cylinder meter is increased from 4¾ to 5 ins., le the stroke is reduced from 5 to 4¾ . The added piston area is enough to ke the car pick up speed much more idly than with the smaller piston diam-r and this increase of power is of

well secured and easily removed. T underside of the chassis, clearly sho the full protection given by this du shield.

Outside dust guards are applied, whi in connection with the mud-guards a run-boards completely cover the und side of the car and keep mud, water a dust away from the passengers and t inside of the car, which is a decided a vantage, and one which is not yet to

at there is no shock in starting, and very slow pace can be had in crowded reets without changing from high gear. he Thomas-Detroit motors are by the merican and British Mfg. Co., Bridgeort, Conn., favorably known for excelnce of workmanship and rigid inspecon. These motors are extremely "flexle," giving a very large range of speeds ith a strong drive thruout.

Internal rear hub drum brakes only are ed, and a very large diameter line-shaft rake is placed at the rear of the gearox. This transmission brake-band is ned with camel's hair felt and is fully rotected by the dust pan, and so is uch less liable to wear than are exosed exterior rear hub-drum brake ands. This transmission brake drum is ins. diameter by 2½ ins. face, and as has the advantage of the gear ratio, nly a small band pressure is needed to ontrol the car, which is a point of great nportance. The rear springs all half liptic are on revoluble perches. They are ½ ins. long by 2¼ ins. wide in the front nd 53 ins. long by 2¼ ins. wide in the ear. The spring seating and retention has een worked out with great care. The orings have leather pads top and bottom. e U-shaped spring clips have 9-16 diamer screws and nuts and the top spring ates are of bronze, grooved cross-wise to ke the clips at each end, making a spring tention which is unusually well adapted resist spring displacement.

The front axle is an 1-section steel drop rging with no welds. No struts are ted. The torsion arm, a steel tube, has s globe front end between cup-washers ith coiled springs top and bottom, all nclosed in a casing. The chassis frame of a prest steel, 5-32 thick, frame de greatest depth 4 ins. It has two idths, 32½ ins. in rear and 31 ins. in ont. The front board is mahogany ⅞-s. thick, flat, for the touring car. For e runabout models, the front board is deep aluminum casting, no wood whatver. The lamps-brackets are all steel rop forgings. The gasoline tank, 18 galns capacity, is carried under the seat, nd is above the carbureter in the tourg car. In the runabouts the fuel tank under a small pressure which is obined from the exhaust through a cool-

The oil basin has two crank-pits, e fitted with an overflow stand-pipe lead to a well below, containing a two-pinion pump driven by the lower end of the c mutator shaft, that forces the oil upw thru a line of piping which has glass sight in the rear of the front bo and then goes down and delivers all oil to the crank shaft middle bear whence it goes to the two crank pits then through the overflow pipes to oil well and pump again. The oilin by splash, and more or less oil is gi to everything by varying the height of stand pipe.

Fig. 6. Thomas Detroit 1908 control; il tration from the runabout. The coil-box lubrication sight-stand under the cowl on shelf rear face of front board. The lubri tion sight does not appear in this illustrati

CONTROL.

The outside lever is latched, and w pulled backward first disengages clutch and then applies the emergency ternal rear hub-brakes. The inside l rocks side-wise in a straight slot an moved to affect the selective gear chan The steering is by a quadruple threa screw, trunion nut and bell crank slotted arms. The spark and throttle trol levers are ratchet retained on to the hand wheel. The left hand pedal leases the clutch only. The right h pedal applies the line shaft brake c and is not interlinked with the clu A plunger pedal governs the throttle sition.

ukee, Wis., which began operations out a year ago, has produced several dels of cars, and is now incorporated l is placing the first of its perfected structions, a three-seated Roadster, on market. The policy of the Hay-Berg mpany is to purchase components of best makers and assemble them in a rmonious design, carefully suited to the t service of the selected elements.

The parts and materials used are of the y best, and the mechanical experiences l successes of the Hay-Berg officers rantee the quality of the workmanship the cars produced under their manage-nt.

A 1908 20 H. P. four-cylinder air-cooled rrico engine is used. The compression only 55 pounds. A three-speed sliding nge speed gear is fitted with cardan ft to the bevel gear drive divided axle. e bodies are of wood, hand-made by the

frame members forward.

The Carrico air-cooled motor is al carried on 3 points only, one in front the front cross-member of the frame, a two at the rear of the motor on the chass frame sides. This gives a good distrib tion of the motor and gear box weight the chassis frame. A universal joint limited movement is placed between t crank-shaft and the line shaft. The clut is an exterior constricting band, co-acti with an exterior cylindrical extension tegral with the flywheel. This clutch pedal actuated in both directions wi one pedal only, and requires no sprin whatever.

A Hartford universal joint is used b tween the gear box and the rear ax Both front and rear axles are by the Ti ken Company, with exterior and interi brakes. No line-shaft brake and no stru are fitted. The change gear is slidin

Fig. 1. The Hay-Berg 3-seat Roadster. Wh eel base 110 ins.; gage, 56 ins.; tires, 34x4 in r; 34x3 1-2 ins. front; motor, four, 4-cycle air -cooled cylinders, by Carrico, 1908 model, 55 lb npression, 20 horse power at 1200 R. P. M.; sliding gear, 3 forward speeds and a revers el gear drive to divided rear axles. Wooden bodies, hand-made by the Hay-Berg Company, t 3 passengers. Weight, 2000 lbs.; price, $2000, including 5 lamps, horn, mat and tool ready for the road.

y-Berg Company. The roadster seats ee people, has 110-inch wheel base, 56 e, and 34x4-inch rear and 34x3½-inch nt tires. The car weighs complete 2000 nds, and is listed fully equipt at $2000.

NOTABLE FEATURES.

he chassis frame is prest steel, A. O. ith Company, greatest depth of side-nes 4 inches, two widths, 34 inches r and 30 inches front. Oblique mem-s are introduced forward of the middle ss-girt, reaching to the offsets in the

selective type, by Brown-Lipe. The stee ing gear is a screw action, powerful a without lost motion.

AIR-COOLING.

Altho there is at this time a sentime in favor of water-cooling, the advantag of air-cooling are so obvious that no o would wish to add the radiator, water c culating pump and cylinder water-jacke to an air-cooled motor which gave no tro ble. As showing what the air-cool motor can do, the first Hay-Berg 5-passe

Digitized by Google

-cooled motor, coupled with its great nplicity and the absence of water, fully termined the Hay-Berg management to opt air-cooling. The writer can add his n testimony as to the good work of an erloaded Carrico air-cooled motor during 375 mile run in dog days with the ther-ometer at 96 degrees and the fan-belt off, e car weighing about 3300 pounds un-aded and carrying three passengers. ese facts, not isolated but merely every-y occurrences which can be repeated at y time, amply justify the Hay-Berg Com-ny's decision to use air-cooled motors in of its cars.

and no aluminum are used for these tails. The inside front mud guards fu prevent splashing.

THE HAY-BERG ROADSTER BODY.

The lines adopted show for themsel in the illustrations given. The form is keeping with popular approval, and th seats are provided; the rear seat can removed, giving ample room to carry l gage or even a considerable quantity goods, and a double seat, accommodati two passengers, is fitted to order, maki a surrey body. As shown in these ill trations the rear seat has ample fo space, which greatly adds to the comf

Fig. 2. Hay-Berg Chassis, mud guards removed. The Carrico motor is fixt to the chas rame at three points only, one at the middle of the chassis frame front cross-member, and t ther two points on the two frame-sides, close in front of the front board.

The oblique chassis frame members, extending to rear from the side-frame bends to t niddle cross-girt, effectively reinforce the side member bends, and also give a convenient loc ion for the gear-box, which is like the motor, fixt to the chassis frame at three points only.

POWER.

This new Hay-Berg Roadster can take l ordinary hills on the high gear, 3 pas-ngers up, and can go anywhere on sec-d speed. The low speed, like the re-rse, is of advantage only under un-ual conditions, as the second speed kes the car thru mud and sand with se and certainty.

The springs are all half-elliptics, 40 in-es by 2 inches, 5 leaves in front and 48 ches by 2 inches, 7 leaves, in the rear. o struts are fitted. The fuel tank, gal-nized iron, 24 gallons capacity, is located der the driver's seat, with the bottom anding six inches above the Schebler reburetor. The fuel tank has a hand

of the rear passenger, or may be used carrying bags and parcels.

CONTROL.

The Hay-Berg Roadster Control is v simple. The steering is by a screw tion, and the spark and throttle levers ratchet retained on top of the hand wh an accelerator pedal being provided on foot-board. The brakes are external internal, rear hub drums of the known Timken construction. There two hand-levers, the outside one shift the gear, while the inside hand le latched, applies the exterior, emerge brakes. The internal brakes are app by the right pedal, while the left pe works the clutch. The clean appeara of the foot-board is well shown in the

It is promp t in starting and very strong on partial charges.

d, Wis., in good time, the motor work- to perfection, and showing plenty of eed and hill-climbing power. Within out 17 miles of Milwaukee, on the re- n run, the car was driven off the road

Fig. 4. Hay-Berg Control. The steering is a screw action, with spark and throtle con- l on top of the hand wheel and an accelera- pedal on the foot-board. The upright hand ers apply the emergency brake and shift the rs. The right pedal works the ordinary ke and the left of the clutch. The oil

tire was removed, and the car driven Menominee Falls on the wheel rim, wh wrecked the wheel, and caused a delay some hours before it could be replaced

In this first run the Hay-Berg roads showed well at every point except in springs, which are the first ones pla and are not what they will be. The ro was very hilly and the motor was push hard, and was always ready to meet demands. The car took hills, of wh there were many in the route, very w indeed, climbing almost everything high gear, but this otherwise most s cessful performance was made unsatisf tory by the accident at the end. The d tance covered was about 75 miles.

A second run was made Monday a Tuesday, September 2 and 3, Milwauk to Janesville, 71 miles and return, rou trip 142 miles, shortest road. The ro ster, supposed to have been thor repaired, left Milwaukee at 8.20 Mond Mr. Sternberg, one of the Hay-Berg ow ers, who has had only a limited expe ence, driving.

About 12 miles out, near Calhoun S tion, on a straight and pretty fair ro our left hand front wheel began to sh its spokes, and some 300 feet from whe it left the first one in the road the c stopt in the right, deeply gullied, d ditch, with the wheel-rim clear of the hu but the car right side up, all the passe gers in their places and nobody hurt. W were running about 20 miles an hour.

Digitized by Google

Much of the road was very rough, towns were few and small, and we had ask our way, which delayed us.

On Tuesday morning we left for Milukee. Our same left hand front tire nt down 7 miles out, was patched, but ted only two miles. Then we put a 3½-h inner tube into the 4-inch shoe, lost road, and our storage battery ran vn while still 40 miles west of Milukee. We procured a battery of dry ls, and proceeded only to have our same hand front tire go flat from the leak- of a patched inner tube. To be safe had our spare tubes patched about 10 es from Milwaukee, which place we trouble was due to bad tube patchin The 3½-inch inner tubes in the 4-in shoe served perfectly well, save for t faulty patch on the first one put in. T 4x4 air-cooled motor was always read prompt starting, powerful and absolute perfect in action thruout. The whole d tance covered was well over 200 miles.

If the Hay-Berg roadster had not be very well put together it would nev have existed after its accident in the fir run. The motor performance was r markably good, and the car showed its to be silent, speedy, a strong hill-climb and of good appearance.

1908 Cleveland Car

The 1908 "Cleveland," made by Cleved Motor Car Company, is offered in models on the same chassis, one a ring car, and one a roadster, each list- at $3500.

The motor consists of 4 cylinders, verl, water-cooled, cast in pairs, with inral water jackets. The bore is 5-inch stroke 5-inch.

gnition is by jump spark, with an imted Bosch high tension magneto, and an auxiliary and independent coil and rage battery. Spark plugs for magneto cuit are over the inlet valves. The used is a single unit "Connecticut" h distributor.

postive feed mechanical oiler is selftained in the motor, and the oil reser- is carried as an integral part of lower f of motor crank case with capacity of ee gallons. Overflow holes in the oil of the crank case keep the oil at a stant level at all times.

Valves are mechanically operated; let and exhaust valves are both on t right hand side of the motor, and are terchangeable.

The cooling system comprises a Ma radiator of new Cleveland type and shap a large gear-driven pump and liberal siz drawn copper water tubes and conne tions.

The gasoline tank holds twenty gallon A large dirt trap is located between t tank and carburetor.

The transmission gear is of the selecti type, four speeds forward and one revers with direct drive on third speed. F and Annular Ball Bearings are used. T clutch is of the multiple disc type, ru ning in oil.

The rear axle is of the floating clut driven hub type, ball bearing thruout.

The front axle is a drop-forged I-bea section. The reach rod between the ste ing connections is located back of t front axle, which is placed flush with fro of radiator.

FORD "SOUND LOGIC" TALKS

WE HAVE BEEN CRITICISED because Ford agents receive about half the discounts for selling Fords that other makers find it necessary to pay in order to force the sale of their cars in competition with Fords.

SEEMS TO US as if that criticism is a boomerang. We fully admit that Ford agents have received less "rake-off" per car—but every one of them more than quadrupled the number of sales of his competitors.

YOU CAN'T POINT to a Ford agent who will handle any other line in 1908—if he can get the Ford. And he can get it if he has "made good" and treated his customers right.

HERE ARE THE FACTS: We believed that a thoroughly reliable, powerful, practical runabout could be built at a price within the reach of any man earning over $1800 a year. We believed $600 ought to buy such a car. And we did build and sell 2,500 at that price allowing usual agent's discounts

COMPETITORS AWAKENED to the fact that they were out-classed. Whether in sincerity or not we do not know, but several announced that they would "meet Ford on his own ground." They began to bid for supplies in the market. This resulted in inflating values—though it brought forth no real competition.

WE FOUND OURSELVES confronted by a severe problem and one which threatened for a while to defeat our plans. The advance in prices of material made it impossible to make cars at cost estimated.

ONE OF TWO WAYS WAS OPEN to us. First, to raise the price. This, our esteemed competitors hoped we would do—our well-meaning friends advised us to do, for Ford cars were commanding premiums as high as $250 and the output could all have been sold for $1,000 per car easily. The other alternative was to adhere to the price, even though, after deducting the regular 20 per cent. agent's discount, it cut our margin to nothing. The first was not to be thought of—principles—Ford principles—don't vary, even if prices do fluctuate. We were committed to a price, and had staked the reputation and all the resources of the concern on this runabout proposition. The price and quality must be maintained—that done, competition was helpless—the cars would sell themselves. This we could do if the agents were willing to divide their discount with the factory. We laid this proposition before our agents. Some assented readily; some reluctantly; a few refused, dropped the Ford line—and are sorry.

WE HAD AN ABIDING FAITH in the sound good sense of the average buyer; we were right; the customers saw where the value was; Ford cars sold themselves. Many Ford agents to-day admit they sold cars over their own half-hearted recommendations and even protests. No customer ever asked for a division of the discount—the news spread and they were getting "all automobile" for their money. No bad trades were made—all that was left to agents getting fancy commissions for selling inferior cars at higher prices.

AND THE NET RESULTS?—the most wonderful season's business ever recorded in the history of the industry.

SEVEN AND ONE-HALF MILLIONS of dollars' worth of automobiles made and sold, placing Ford in the first place among makers of the world.

Hosted by Google

And Some PERTINENT FACTS

THE MOST WONDERFUL RECORD of performance, economy of operation and up-keep of pleased, delighted customers ever known to the trade.

DID FORD AGENTS MAKE MONEY?—ask 'em what line they will handle next year!

AND THE FUTURE?—Recent events have had a sobering influence on the market and especially on makers of parts and supplies. The price of copper has declined; other materials are seeking their natural level. Ford facilities now enable us to make every part of the car except tires, wheels, coils and the paint that goes on the body.

WE MAKE OUR OWN STEEL—Vanadium steel—and in this we stand alone among makers of the world. Thirty-five hundred tons of Ford Vanadium steel now under way.

FOR 1908 WE WILL BE ABLE to maintain the standard of quality to the customer and divide a more liberal margin with agents. Ford agents can continue to offer their patrons one hundred per cent. better values than any other—won't tell you what it is yet, but it's Ford and that's always two years ahead.

WE ARE NOW READY to establish an agency in every city, town and hamlet in the United States.

THERE ARE A FEW THINGS we'll insist on: In towns large enough to justify it the agent must maintain a repair shop, must carry a stock of small parts for replacements, must treat his customers liberally, fairly and courteously—we've had enough of those short-sighted "penny wise and pound foolish" fellows, who charge a good customer for adjusting his carburetor or cleaning a plug—they never get anywhere and they misrepresent Ford policy.

WE WANT MEN OF GOOD REPUTE IN THEIR HOME TOWNS—good, reliable hustlers—mechanics preferred—who will properly represent "Ford Courtesy" as well as Ford cars. We want men who will go into the automobile business in earnest, who will lay plans for the future—men who appreciate that the motor car is no longer a luxury, but an everyday necessity to every business man who isn't rooted to one spot all day. We'll treat you right—copy that in your dealings with customers and you'll win. Ford cars sell themselves, and you'll easily place five Fords while trying to force one of the others on an unwilling customer.

LARGE CAPITAL IS NOT NECESSARY to obtain the agency—we don't tie you up with a big contract for a large deposit or insist on your disposing of a definite number of cars—we know you will sell as many as we'll give you and we'll give you all you can sell, promptly. Good reputation and good intentions, backed by hustle and cash to pay for cars as you order them are the only requisites. The 1908 Ford line will be the most complete, the most comprehensive and the best value ever offered by any maker in the history of the industry.

WRITE TO-DAY for list of towns that are open in your state. Do it to-day—if you delay some more enterprising man or concern will have "sewed up" your territory.

FORD MOTOR CO., 254 Piquette Ave., DETROIT, MICH.

Hosted by Google

protected. The brake shoes are double acting, holding either backward or forward in both the emergency or foot brakes; both brakes are bronze against steel. The emergency brake lever pulls toward the operator to set the brakes, and automatically releases the clutch. The foot brake does not release the clutch. A ratchet sprag is provided on the driving shaft drum. The pawl of this ratchet sprag has a unique spring cushion construction, which prevents shocks to transmission and rear axle when the sprag is applied.

The frame is cold rolled prest steel, channel section. The drop frame is arched over the rear axle. The front springs are semi-elliptic, and the rear are of the three point platform suspension type. The hood or bonnet is 16 gage aluminum. The radiator and dash hood flanges have raw hide lacings to prevent rattling.

CONTROL.

Spark and throttle levers of new and distinctive design are located on the steering wheel. The segment is stationary and independent of the steering wheel. Foot accelerator is independent of the hand throttle lever. The steering wheel rim is of mahogany, 18 inches in diameter, with an aluminum spider.

The wheels of the touring car are: Front, 36x4 inches; rear, 36x4½ inches. The roadster wheel equipment is: Front, 36x3½ inches; rear, 36x4 inches. The touring car wheel base is 122 inches; roadster, 110 inches; and tread, 54½ inches for both. The dash is mahogany bound with solid brass moulding. The body has metal panels, is a seven-passenger type, "straight line" pattern. The price of the touring car or roadster is the same, $3500.

The Albany Runabout

The Albany Automobile Co., Inc., of Albany, Ind., U. S. A., are marketing a line of high wheeled friction driven cars known as the "Busy Man's Car," There are four models, B, C, D and E, $375, $450, $500 and $650, respectively. The motors are a single cylinder vertical, 4-cycle, 4½ bore by 4-inch stroke, rated 6 to 7 H. P., and a twin cylinder, 10 to 12 H. P., 4-cycle motor of 4-inch bore and stroke. Both motors are air-cooled, having integral cast flanges and a belt driven fan. The inlets are automatic, both valves being in the head. Splash lubrication is used.

A description of Model C will sufficiently cover the other models. The wheel base is 90 inches. tread 56 inches; 32-inch artillery wood wheels with steel channel rims and solid 1¼-inch side wire tires are used. The road clearance is 12 inches. The frame is of angle steel, and is mounted upon four full elliptic springs. The front axle is heavy steel tubing, with drop-forged steel knuckles and yokes. The rear is tubing encasing a 1¼-inch live shaft, the drive from the countershaft being a single chain to a Warner differential on the rear axle. Roller bearings are used. The motor in each model is mounted at the front under a hood with the flywheel at the rear, and on an extension of the engine shaft a 20-inch friction disk drives an 18-inch friction wheel, which slides on the feathered countershaft. The disk is metal faced and the wheel is faced with a special tarred friction fibre. All speeds from 2 to 20 miles an hour are operated by one lever. The disks are engaged by a ratchet foot pedal. The disk is provided with a thrust ball bearing, and in the central position the friction wheel acts as a brake. The cars are fitted with a wheel steer, the connectink links having ball and socket ends. The knuckles and yokes are drop forged.

Ignition is by jump spark from a double coil and dry batteries. The engine is controlled by spark and throttle from the top of the steering wheel.

Model C is a two-passenger car, the space back of the seat being used for luggage. Model E is fitted as a surrey, and has running boards, and can also be fitted with a folding top if desired.

Ordinance to Create an Auto Commission

Milwaukee will probably be the first city in the United States to have an automobile commission.

An ordinance was introduced to create a commission, to be composed of three members, an electrical engineer, a practical machinist, and the secretary of the civil service board. All drivers will be compelled to secure licenses, and upon just cause the commission will have power to revoke such licenses. One provision of the ordinance is the right given the commission to revoke licenses of chauffeurs convicted in court of drunkenness.

Cars Insufficiently Marked by the Manufacturers

The manufacturers in this country are not over-careful in marking their cars. The maker's name and the serial number of the car are usually placed on a superficial plate attached to the body, while the engine change gear case, etc., bear no definite marks of the date of manufacture. Under these conditions it is easy for unscruplous dealers to make over and palm off on unsuspecting persons an old car for a comparatively recent model.

Mr. George K. Wheeler, of Columbus, O., sales manager of the Columbus Buggy Company of that city, died of heart failure at 2 P. M., Saturday, August 24.

Hosted by Google

alo, New York, U. S. A., has a factory ntirely separate and distinct from that f the E. R. Thomas Detroit Company, akers of motor cars, although Mr. E. R. homas, of Buffalo, is president of both oncerns. The lines of production of hese two companies differ, in that the uffalo shops turn out larger and more ostly cars than are built at the Detroit actory, though in quality the cars are ntended to be the same.

This description is of the Buffalo prouct exclusively, that of the Detroit shops eing separately illustrated and described.

The E. R. Thomas 1908 Buffalo car nodels are four in number, a six-cylinder ouring car, two different models of fourylinder chassis, and a "Town Car," or notor cab, a closed car on a fourth hassis. This article will illustrate and escribe the two 4-cylinder touring cars

tails.

The outside appearance of the Thomas F and DX models is shown Figs, 1 and 2. Model F is a seven-pas ger touring car with 127 inches w base, 56 gauge and 36-inch wheels, 4-inch front and 5-inch rear tires. motor is 4 cylinders vertical water-coo four-cycle, 5½ inches square, rated a H. P.

The drive is a sliding gear, four ward speeds and a reverse, with side c driven rear wheels. The motor has a in front and the steel casting fly-whee provided with integral fan vanes. seven-passenger body is of sheet a inum on a substantial wood frame steel angles and braces. The tonn seat is unusually wide and two fol seats are placed on the tonneau f which has ample foot space, and the

Fig. 1. The E. R. Thomas 1908 Model F seven-passenger touring car, wheel base 127 ches, gauge 56 inches, tires 36-4 inches front and 36x5 inches rear; motor, four, 4-cycle cylind water-cooled, 5½x5½ inches; nominal 60 H. P. The clutch is 3-discs, one of steel on each s of a bronze disc with cork inserts, double chain drive. Weight, 3000 pounds; price, $5000, w complete equipment.

nly, which have each four cylinders of he same bore and stroke, but have yet naterial differences in the engines, in the heel-bases and construction generally, hich make them two distinct and separate cars.

Of these two Thomas 4-cylinder 1908 ars. known as the "F" and the "DX," he Model F is the larger, 127 inches heel-base, and the DX is the smaller, 18 inches wheel-base. Both the DX and he F models retain the distinctive featres of former Thomas cars, including ymmetrical cylinders with two camhafts and directly operated valves, the hree-disc clutch, the three-point gear box upport, and the ratchet and pawl arngement which acts to prevent the cars

design has been changed to the "stra line" effect, all making this model one o largest, most powerful and most ele of motor cars. The car weighs pounds, and the price is $5000, inclu 5 lamps, mats, horn, complete set of t tire irons and acetylene gas tank, ready for extended touring. The cape is extra.

The model "DX" seven-passenger t ing car has 118 inches wheel-base, inches gauge, and the same sized wh and tires as the model F. The moto also the same size. The drive is a ing gear, four forward speeds and a verse, with side chains to the rear wh The body seats three passengers in rear, has two folding chairs in the

NOTABLE FEATURES.

While the two Thomas 1908 models here strated and described show no radical nges, and, save in the carburetor, no olute novelties, they do show almost nplete re-designing of details through- . The carburetor shows new details ch are regarded as important. The ssis frame sides have been consider- y increased in greatest depth, from 4½ hes to 5½. The side frame width has n increased from 1½ to 1¾ inches, the ckness of stock remaining 5-32, as in 7. This very material increase in both depth and width of the chassis frame been accentuated by increasing the th of the lower member of the channel me sides where advantageous; the gely increased chassis frame strength stiffness thus obtained making it safe omit the ½-inch diameter turn-buckle ss rod, with two king-posts, which has n a distinctive feature of the Thomas ssis frames up to the present time.

The front axles have been re-designed, le the rear axle gearing has been ma- ally improved. All front wheels are Timken rollers, while the change gear, ss-shaft and rear wheels are on stand- ball bearings.

AXLES.

The front axle is the same in models F

The rear axle is the same for mode F and DX, and is an I-section steel dro forging, same as the front axle. Th beam section is 2¾ inches deep by 1 inches wide, web ¼ inch, ribs 5-16, wi large radius fillets. The largest diam ter of the tapered rear axle is 2 5-16 i ches. The rear wheels are on standa ball bearings, 9-16 balls inside and 7- balls outside. The inside ball race against a shoulder, and a tapered ste distance tube is placed between the ou side and inside ball races, so that one n and one washer retain both ball-races. N

Fig. 2. The E. R. Thomas 1908 Model "DX," seven-passenger touring car, wheel base 11 ches, gauge 56 inches, front tires 36x4 inches, rear tires 36x5 inches; motor, four, 4-cycle, water- oled, 5½x5½ inch cylinders; nominal 60 H. P. The drive is by side chains. Weight, 300 unds; price, including five lamps, mats, horn, complete with equipment and gas generator 000.

thrust bearings are fitted. The rear h brake drum is 13½ inches, inside diam ter, internal shoes only are used. Th are fiber faced and cam-rocker expande

SPRINGS.

Models F and DX are equipt with ha elliptics. The front springs are 40 i ches long by 2¼ inches wide, tongue grooved and banded, have 7 leaves, a are jointed to the chassis frame in fro and linked in the rear. The rear sprin are 54 inches long by 2½ inches wi tongued, banded and grooved, have leaves, and are linked to the chassis fra at both ends.

Lubrication of the spring eyes a bolts is cared for by placing finished ste

steel, 5-32 thick, 5½ inches greatest depth, 1¾ inches wide, while the lower channel member is increased in width at certain places. The one-half inch rod and turn-buckle bracing previously used has been omitted. The frame is 174 inches long, spring eye to spring eye, is in two widths, 31 inches front and 34 inches rear, and has five cross-members, with an angle steel sub-frame, 40¼ inches long by 20⅝ inches wide, on which the motor

Fig. 3. Thomas 1908 Front Wheel and Axle-end Construction. The yoke opening is 5 inches. The stub axle pins are one inch diameter, and have hardened and ground ends in hardened and ground bushings. Note the large fillets shown in the I-beam axle section. The front axles are the same in Models "DX" and "F," and are steel drop forgings without a weld.

is placed. The top of the chassis frame is flat, and stands 5 inches above the top of the sub-frame.

The model DX chassis frame is 160-9-16 inches, spring eye to spring eye, is 30 inches wide in front, 34 inches wide in the rear and the frame sides are 4½ inches greatest depth, and made of 5-32 stock. This DX frame has four cross-members with no sub-frame, the motor being carried on four bronze brackets riveted to the insides of the frame sides.

THE MOTORS.

The DX model motor is not very much changed from that of 1907. The cylinders are the same dimension for the F and the DX, 5½x5½ inches, 60 H. P. nominal. The four cylyinders are individual units, with integral water jackets and heads, a plug in the top covers the large core-print opening. Abundant water circulation room is given everywhere, both intake and exhaust valves being jacketed. The water circulation is by a 2-pinion pump.

The cylinders are symmetrical, with valves on each side, all valves the same, directly actuated from two cam shafts. The cam rollers are in forked lifters, which have individual coiled springs in bronze lifter sleeves. The roller forks are threaded at the top end to take capped, threaded length-adjustment sleeves, which are check-nut retained. The valves are all integral head and stem steel drop-forgings, all ports 2 7-16 inches diameter. The crank-shaft journals are all the same diameter, 2 inches, the crank pins are 1⅞ diameter, and the shaft has five bearings in split babbitt boxes. The grey iron pistons are 6¼ inches long with four eccentric snap rings, cut 45 degrees, placed all above the piston pin, and pinned. The connecting rods are steel drop-forgings of grey-iron—bushed at the top end, full marine type with babbit half-boxes and two cap-screws on the crank-pins. The crank-shaft has an integral flange and projection at the rear end to take the steel casting, fan-vane fly-wheel, which is also the principal clutch member. The cams are applied to the cam-shafts and retained by riveted taper pins. The cams are drop-forgings of high carbon steel, case-hardened and ground. The cam-shaft is soft steel, ⅞ diameter. The cam-shaft gears are steel castings and fiber, and the crank-shaft pinion is steel, applied, keyed, and nut and shoulder retained. The cam-shaft gearing is 8 D. P. direct, no intermediates.

Two complete systems of ignition are furnished. the Atwater-Kent and Bosch magneto, with storage battery and jump spark plugs. The Atwater-Kent is held in high favor by the Thomas engineers, it having given excellent results in the past season.

THE NEW CARBURETOR.

In the sectional illustration given the auxiliary air intake assembly is revolved 90 degrees from its actual position to give an intelligible sectional diagram. This carburetor belongs to the float-feed, suction-operated, auxiliary air-intake class, and has a single nozzle. Referring to the cut at the right is shown a screened fuel-intake to the float chamber and a hand-adjusted, screw-threaded needle-valve in a stationary stand-pipe opening to an inserted throat. At the left side of the vertical charge-passage from the carburetor throat to the throttle a port is cut which opens to two vertical concentric cylinders of different sizes, the larger one above the smaller and having an applied cap fitted to the top end of the larger cylinder, and a small open-air hole drilled through the annular wall which unites the two cylinders. The lower cylinder is pierced by six air-ports, open to the atmosphere. The top larger cylinder is fitted with a cup air piston connected by a tubular piston rod to a sleeve valve, normally covering the six air ports in the lower smaller cylinder, all so that when the top air piston is lifted two separate effects take place; (a) the air above the air-piston in the top cylinder is compressed; (b) when the rise of the air-piston has reached a certain height the sleeve-valve in the lower cylinder begins to open the 6 air-ports of that cylinder so as to establish a communication between the passage from the carburetor throat and the throttle to the open air, reducing

Hosted by Google

the richness of the mixture. The air-piston is lifted by the suction of the motor, but its motion is resisted (a) by gravity, (b) by the compression of the fixed volume of air above the air-piston, and (c) by the lack of air below the air-piston, which air to supply the space below the air-piston must enter at a rate determined by the diameter of the small air-hole in the bottom of the air-cylinder. These conditions cause a weakening of the mixture when the motor reaches a certain speed, and its continued weakening so long as the motor speed increases. The small area of the air-port admission under the air-piston and the trapped air above the air-piston combine to prevent fluttering and sudden fluctuations in the auxiliary air supply. The tubular air-

Fig. 4. The 1908 Thomas Carburetor. This is a new design, and has an auxiliary air valve of the piston type without any springs. For complete description see text.

piston rod opens the air-cylinder above the air-piston to the piston suction. The resultant action of the whole of this simple and positive carburetor auxiliary valve action, which has no springs whatever, is to make the mixture less rich when the motor runs fast than when it runs slow, and to vary the charge-richness gradually both ways, without sudden or fluttering fluctuations.

THE CLUTCH.

The Thomas fly-wheel is a steel casting, having integral exterior fan-vanes, and a friction surface which coacts which a bronze ring with cork inserts and a second steel ring, all prest together by four levers and the clutch spring, or relieved from friction by the action of the clutch disengaging pedal. The spring required is light, only about 350 pounds tension, and the clutch is very soft in engagement and gives a wholly satisfactory slipping drive.

THE CHANGE GEAR.

The selective change speed gear is four speeds forward and a reverse, direct on the high gear. The box is an aluminum casting, with applied annular ball-bearing seats of bronze, retained by pouring with fusible metal specified as "Babbit." The bronze ball-bearing seats are first machined inside, and then placed on jig-arbors and babbitted in place in the aluminum gear-box, making all the gear-box center distances alike and as nearly accurate as possible. The gears are all 6 D. P. high carbon steel, the idle gears being free on the high speed. The balance gears are bevels, and the counter-shaft members have universal joints of limited range, which engage the sprocket shafts carried in annular ball bearings in brackets fixt to the side-frames.

The steering gear is a carefully and substantially worked out worm and sector action. The sector is cut on two centers to make the middle tooth the highest. The rock-shaft is on Timken rollers and the worm thrusts are taken on ball bearings. A feature not usually seen in steering gears is the two temper-screws, check-nut retained, which limit the motion of the worm gear sector in both directions so that the steering wheels cannot be turned too far either way.

The turn-buckle length-adjustment is very largely used in the Thomas 1908 details, and all nuts have special retentions, principally castellation with split-pins, tho some check-nuts are fitted.

CONTROL.

The steering is by a worm and sector with spark and throttle levers on top of the hand wheel. There are two outside hand levers, both latched. The outside lever is pulled backward to first disengage the clutch, and then apply the internal rear hub drum brake. The inside hand lever shifts the gears. There are two large pedals, an accelerator pedal and a muffler cut-out plunger pedal. The right large pedal is pushed forward to apply the counter-shaft brakes, and the left large pedal to disengage the clutch. The accelerator pedal is horizontal, and located between the two large pedals. There are no outside rear hub drum brakes. The counter-shaft brakes, two in number, are fixt to the two counter-shaft members, and have fiber lined, constricting bands, applied by the right large pedal thru an evener, so as to give equal resistance to the turning of the two rear wheels.

Morgan & Wright, Detroit, Mich., have opened a branch at 118, 120, 122 East Tenth street, Los Angeles, Cal., for the accommodation of their Southern California trade.

Empire State Tire Company, 73-77 Erie County Bank Building, Buffalo, N. Y., has recently organized and secured the rights in New York State to manufacture the Greenwald tires, tire protectors, non-skid treads, and sectional vulcanizers.

A Strong Statement—but a True One about the

The distinguished successes of the present automobile season, you can name on a very few fingers. And however you name them, the Elmore must come first.

First, we mean, in point of swift sales; the quick clean-up of the entire output; the call for more cars than our big plant could build; and the magnificent satisfaction which every Elmore in use is giving its owner.

Each Elmore season has surpassed the previous one---each year has seen its prestige grow greater and greater and greater.

In 1908, we promise you that the Elmore will be the most perfect car of its class in America.

CHAS. E. DURYEA

QUESTIONS ON THE DESIGN OF A VIBRATIONLESS MOTOR.

Indianapolis, Ind., July 13, 1907.

I am going to build a small double-cylinder opposed motor. I want to build it so as to eliminate all vibration, if possible. I intended to make the bores of cylinders 2 inches, and the stroke 3 inches. Now this 3-inch stroke is rather large for the bore, but I had an idea that the reason that most gasoline engines vibrated was because the exhaust valve was not opened soon enuf. Now I am going to open my valves about ¾-inch before the end of power stroke, so that when the crank gets to the bottom all the pressure will be released and the crank will pass easily around without any jerk at the bottom. Please tell me what you think of this theory. I don't care for very high speed, 900 is enuf, and a great amount of power is not essential, what I want is the least vibration possible. Will the engine be perfectly balanced if the cranks are set 180 degrees apart? If that stroke is too long what would you suggest? What size and weight fly-wheel would you suggest to make the motor run very evenly and steadily? Are ⅞-inch valves all right? Would a water space ¼-inch thick and 2 inches long around each cylinder be enuf to cool the motor? What kind of piston rings would you use and how many? If 3-inch stroke is all right how much clearance between the top of the piston and the cylinder head would you have, and if you suggest a different stroke what clearance then would you leave? Would you put a separate oiler for each cylinder or what method of lubrication would you use? What size shaft and crank pins would you use? If possible and if you have time would you please make diagram of ignition apparatus using one vibrating jump spark coil for both cylinders. Is this method as efficient as individual coils for each cylinder? I would be glad to get any other pointers about this engine that will make it smooth running. Also let me know what H. P. I may expect.

A. J. M.

A 2-cycle opposed motor if carefully balanced will eliminate most of the vibration. Better buy a couple of bicycle motor cylinders and save cost and experiments. You are wrong about the exhaust causing the vibration. The kick of the explosion is the cause and it pushes the motor as hard one way as it pushes the fly-wheel the other. Make the fly-wheel light and it will move instead of moving the motor and its frame. More cylinders to get a steady torque is the only sure way to kill the vibration. The long stroke will not help either. Your valves and water jacket are all right and you will get less vibration by using low compression. Make the compression space 1¼-in to 1½-in. long. A 12-lb., 12-in. fly-wheel should serve and lighter might serve better, particularly if you never want to run slowly. A separate oiler on each cylinder will serve nicely. You can get most sizes by looking at a good cycle motor at some repair shop or by reading descriptions in this journal. A single coil with a distributer to send the high tension spark first to one plug

A B—Metal segments on mica disk.
C C C—High tension wires, the middle one from the coil and the others to the plugs.
D—Insulated post to hold wires so their points terminate near the segments on the disk.
The spark will pass thru one segment to one wire one time and thru another to the opposite wire the next time.

and then to the other is a first-class arrangement. A simple form can often be rigged up by using a sheet of mica with two foil or brass segments on it and letting it revolve with the cam shaft (see sketch). Or coil makers can sell you a distributer. Two coils are no better and are harder to adjust alike. C. E. D.

A CASE OF POOR CONTACT.

New Knoxville, O., July 27, 1907.

I have a Kent volt and amperemeter on which I would like to have a little information. If I connect a new battery to the meter, that is, put the wire on the zinc side and the part marked carbon on the carbon it measures about 6 amperes, but as soon as I connect the carbon side on the brass binding post on the carbon it measures about 16-18 amperes. What causes this? L. H. MICKSHOTH.

When you put the "carbon" pole of the meter against the carbon of the battery you do not get a good contact and so do not get a full flow of current. The brass binding post is much larger and gets a better contact and more current flows thru it. Just imagine how a water pipe would behave if it was badly choked. This illustrates the necessity of having full size wires and good connections at every point if the best service is wanted. C. E. D.

WIRING USED WITH EISEMANN MAGNETO

Pawtucket, R. I., April 12, 1907.

I beg to take advantage of my perquisite, as an old subscriber to the "Cycle and Automobile Trade Journal," to ask you if you will kindly give me the outline of the wiring, for dual ignition, as used on the Pope-Hartford machine this year, with the Eisemann magneto and the Eisemann-Carpentier coil? The car is also fitted with the usual timer which is of the Lacoste type. FRED G. PERRY.

WIRING DIAGRAM FOR EISEMAN-CARPENTER SYSTEM WITH TWO SETS OF BATTERIES AND EISEMAN TYPE MAGNETO.

The sketch herewith is a copy of that furnisht by the makers and I trust will meet your needs. C. E. D.

BEST DOCTOR'S CAR?

McKeesport, Pa.

What in your unbiased opinion is the best car on the market suitable for doctor's use in a very hilly country? What do you think of solid tires on a car weighing about 1400 lbs.? How about water against an air-cooled car for doctor's use? Will you kindly send me your opinion real soon, as I am thinking very seriously of buying, but thought I would consult some one that knew best just what was best for me. I am a subscriber to your Journal, altho I am not an owner of a car.—DR. W. C. BAIRD.

We cannot specify any particular vehicle as best, for this is but a matter of opinion. The writer's opinions are exprest by the vehicles he has been building. The better principles for your purpose can be exprest as follows:

A hilly country requires ample power. Remember, however, that 40 horse power on a 4000 lb. vehicle is not as good as 10 horse power on a 1000 lb. vehicle; so the mere amount of power itself is no guide whatever, but the amount of weight carried must also be considered. The heavy vehicle sinks into the soft road and is at a great disadvantage because of this fact. It therefore requires more power in proportion to its weight than does the light vehicle. Solid tires are not to be selected because of the weight of the vehicle but for other reasons. It is customary to equip light vehicles with pneumatics and heavy ones with solids. Pneumatics to-day will carry light loads nicely and those who have tried both have usually continued the use of the pneumatics, particularly if the roads are rough. On smooth roads, the solid tires run beautifully. For speed below 10 or 15 miles per hour the solid tires also serve, but at high speed the pneumatic is nicer.

There is much to be said in favor of the air-cooled, yet many air-cooled cars have been abandoned by their makers in favor of water-cooled. This does not say that they are not so good, but simply that the water-cooled is alright and buyers are a little doubtful about the air-cooled. Air-cooled cars can show performances equal to and in many respects superior to water-cooled, so there is no objection to a properly built air-cooled car. Unfortunately, makers have often assumed that air-cooling is not fit for anything but low power, and have not used the good judgment in connection therewith that has been expended on water-cooled vehicles. One reason often is that the buyer purchases an underpowered air-cooler, works it to death and then blames the air-cooling system. A good motor should be machined inside and out, so that its cylinders are known to be equally thick all around. If this is done, the air-cooled will expand equally and will give just as good satisfaction as the water-cooled. Further, it avoids complication, which is of advantage to a doctor. The best advise to a purchaser is to select the vehicle that most nearly seems to meet your needs and then get in touch with users who have been using this style of vehicle for more than a year. Their advice will generally be unprejudiced and reliable. If possible get the address of the users, from some source other than the manufacturers, so as to prevent the selection of successful users only. The Journal of the American Medical Association has published a Doctor's Number, as has also one of the weekly automobile magazines. These issues will assist you in your selection.—C. E. D.

COMPARATIVE HEAT VALUES OF FUELS.

Elizabeth, N. J., May 7.

I would like to know if you can supply me with the information in regard to the following subjects:

About how many heat units are there contained in each, a pound of anthracite coal and a pound of calcium carbide?

Also, which flame throws off the most heat units, all flames being the same size, an acetylene, gasoline, alcohol or an ordinary gas flame?

I take it for granted from what I have read about gasoline and acetylene when used in motors, that the acetylene generates the most heat, because it is difficult to keep a motor cool when using same.

Hosted by Google

Chicago Cleveland

The Auto-Meter Won in the Glidden Tour

New York

Won in 1906 Won in 1907 in the Glidden Tour

Last year 38 out of 62 Cars entered in the Glidden Tour were equipped with Warner Auto-Meters, as compared with 55 out of 74 this year. At the finish last year 10 Cars out of 13 with perfect scores had Auto-Meters, and this year 36 out of 48 Cars that finished had Auto-Meters.

Won in the Sealed Bonnet Contest

Out of 68 Cars in the Chicago Sealed Bonnet Contest, 26 had Auto-Meters—the nearest competitor of the Auto-Meter had only 16 and the next 14, the next 7 and the rest —"nowhere" with 2 and 1 each.

Practically all Route Books Are Compiled by Auto-Meter

including *Motor Guide, The White Route Book,* Sidney J. King's Book, and the Routes issued by the *Automobile Club of America.*

From start to finish in the far-famed Glidden Tour this year the **Warner Auto-Meter** helped to win most of the perfect scores for the contesting cars. The **Auto-Meter** was installed

On 55 Out of 74 Cars AT THE START

in Cleveland. In this awful endurance test of keeping absolutely accurate figures on "How Fast" and "How Far" to Chicago, and then on to New York under some of the fiercest road conditions, there were **36 Auto-Meters on the 48 Cars that finished** at New York—**75 per cent** of the **Winners.**

Victory for The Warner Auto-Meter

On 36 Out of 48 Cars AT THE FINISH

That's going some. It's a victory for the **Auto-Meter** which might have been anticipated, because—

The magnetic principle which makes the **Auto-Meter** as reliable as a mariner's compass makes it unnecessary for the shaft to run at such a *wearing* high rate of speed, as on other speed instruments.

Consequently, experienced Motorists, like the Glidden Tourists, know that the **Auto-Meter** is the instrument that can be *depended* upon to stand hard endurance runs and *accurately tell* the *speed* and distance made by a car *from* start *to* finish without wearing out or being put out of commission like others.

That is also the practical reason why you'll see the **Auto Meter** on the *Cream of all Cars* on any road.

Watch any line of Motor Cars anywhere—you'll see the handsome little **Auto-Meter** on the dashboard of the best of them and the most of them—then you'll decide that

You ought to have an Auto-Meter on Your Car.

Agencies in All the Principal Cities

Won in Almost Every Contest

The Auto-Meter is so immensely popular with motorists everywhere, and it is so universally used and depended upon to tell speed and distance figures, that it is only natural that it should be used by experts in all great contests and win the most victories.

Won the Chicago Reliability Run and Boston Endurance Race

In both of these hard tests the **Auto-Meter** was used by the majority of the entrants, and proved absolutely dependable under all trying conditions.

The Warner Instrument Co., 721 Roosevelt St., Beloit, Wis.

Write Us the Model or Power of Your Car for Price Ready to Install.

Hosted by Google

I would particularly like to have the information regarding the various flames.—W. W. HARRISON.

The heat values of the substances mentioned are about as follows: Anthracite coal 14500 B. T. U., petroleum 19260, gasoline, according to the density, varies slightly from this petroleum figure. Alcohol (denatured) 13150. Calcium carbide is not a fuel, but must be mixt with a little over half its weight of water, when it produces about 5¾ cu. ft. of acetylene C2 H2 gas. This gas has a heat value of 18260 B. T. U. per lb., but requires about 3 lbs. of carbide to make a pound, so it will be seen that 1 lb. of carbide plus ½ lb. of water contains 6085 B. T. U. It slacks easily when exposed to air and will not give its rated capacity of gas under ordinary conditions. 5 cu. ft. per lb. is usually figured.

The acetylene flame is much hotter than the other flames mentioned. If acetylene gas and oxygen are properly combined in a blow pipe, the flame will cut steel like an electric arc. The acetylene light is very intense because the carbon particles are both plentiful and heated very hot. In some recent tests made in Paris the following heat efficiencies were found: Alcohol 24 to 28 per cent., gas 18 to 31 per cent., gasoline 14 to 18 per cent.—C. E. D.

A ROTATING MAKE AND BREAK MECHANISM.

Portland, Indiana, July 6, 1907.

We are very enthusiastic advocates of the make and break system of ignition for gas and gasoline engines, and highly value your views on the subject as given in the "Cycle and Automobile Trade Journal."

As a result of some five years of experience upon ignition systems, we present the design shown in the rough sketch, as the best in theory and practice known to us. We wish your expert opinion upon the merits of the system.

In this sparker the following advantages over others working on the same principle, can readily be seen:

Placing large jaw and spring connecting the jaws, upon a bushing or the like, in which the sparker shaft is inserted, instead of upon the sparker shaft itself.

Moreover, there is nothing to hinder the quick and lively action of the sparker shaft. Sparker shaft is well supported and is also very compact in design.

We have always been in favor of using rotary motion in the place of reciprocating motion, when possible. For this reason and because the timing of multiple cylinders can be accomplished by a single timer more easily and simply, we use the rotating actuating means rather than individual reciprocating rods, as is common practice at present.

This timer has been most successful and reliable. Main feature is, wide variation in the time possible. Thus one is enabled with an engine or four or more cylinders to start (if, of course, the cylinders have retained ignitable charge) by retarding and advancing, thus catching the cylinder on the down stroke which has

just past compression. Or one can manipulate the timer so as to catch the cylinder just coming up on compression. Thus making a back kick and compressing the cylinder which was on the down stroke, and then immediately firing the last mentioned cylinder so as to set the engine going in the proper direction.

We are very confident that this is a system well worth the introducing and would thank you very much for your opinion and any advice you may offer.—CHAS. C. COULSON, H. G. COULSON.

The make and break ignition system has a number of advantages not secured by the jump system. It is not so easy for the motor builder to apply as it is to buy jump spark parts in the open market, so it is not found in many of the cheaper motors. Your design seems to combine the usual hammer break in the cylinder with a rotary shaft for operating the several igniters. The rotary shaft idea is not new. It has been used on an auto engine made in Buffalo for several years and also on many boats for several years. Your method of varying the relation of the shafts to each other is new to me and quite likely patentable. A spiral collar of some sort is usually used for this purpose. There may be other features not clear in the small sketch, which you can patent. Possibly some manufacturer that sees this description will find it convenient to write you. The idea certainly looks practical and can be made to give satisfaction.—C. E. D.

AIR-COOLED ENGINE DIMENSIONS.

Evanston, Ill., July 1, 1907.

As I am about to build a 4-cylinder, 4-cycle, 3½-in. bore by 4-in. stroke, air-cooled auto engine, I would like a little information regarding same. I have a motor with valves placed in the head.

Are ⅞-in.x⅛-in. flanges 3-16 in. apart sufficient for cooling this cylinder?

Are 1⅛-in. valve openings with 1-in. exhaust and inlet pipes sufficient?

Is ¼-in. sufficient valve opening?

Are ¼-in. walls and head alright?

With ¾-in. compression space, should the motor develop 15 H. P. at 1000 R.P.M.?

Is a 50-lb., 20-in. flywheel large enough?

The valves are so arranged that in order to get the spark plug in the head it must enter on a slant about ¼-in. from the cylinder wall.

Would you prefer it on the side, as in the Franklin?—DE SILVA.

Your engine design is all right. The amount of cooling surface needed depends upon the amount of air reaching the cylinders. The more air the less surface needed. I would suggest a larger exhaust pipe, but if not convenient the 1-in. will probably serve. I do not think you will get over 12 horse power at 1000 R.P.M. The flywheel will be found amply large. I would prefer the spark plug on top, as you mention.—C. E. D.

1908 MOLINE 1908

THE changes in the MOLINE line for the coming season are such as to make the Four Cylinder Cars very much more handsome in general design, more quiet running, and more powerful in action.

The same high standards of workmanship are maintained as to details of construction, upholstering, and painting so that MOLINE cars are second to none in the American market.

The Two Cylinder Car has given such unqualified satisfaction that it is being continued for 1908 in exactly the same style and at the same price. It is positively the best looking and easiest riding two cylinder in the market. On the question of speed and power you may judge for yourself, our catalogue gives the size of the cylinders and names the actual weight, and we stand ready to make demonstrations any time.

We are open for agencies in a few good cities.

A QUESTION OF MOTOR AND CLUTCHES FOR A TRACTION ENGINE.

Minneapolis, Minn., July 29, 1907.

Being a regular purchaser of the "C. & A. Trade Journal" I take the liberty to ask a few questions, also an answer by mail, as my questions are not of general interest. I am sending two sketches of gasoline engines that I wish you to pass your opinion upon. Not being a draughtsman, perhaps I have not made everything clear to you. No. 1 is a double-opposed motor with two fly-wheels and an extra long crank shaft extending to the right side. Upon this shaft and all inside of the bearings I wish to mount two friction clutches, both to be operated by one lever, thus doing away with the danger of some one trying to use both clutches at the same time. The gears attached to these two clutches will mesh with gears on a counter shaft placed below and attached to the frame of the truck and from this counter shaft power

Fig. 1.—Double opposed motor 4-cycle, about 20-H. P., make and break spark throttle governed, speed from 150 to 500 R. P. M., mechanically operated valves, motor to be used for gasoline traction engine, weight no objection. Good transmission and a one-lever operated variable speed and a powerful engine is the object.

Fig. 2.—Twin cylinder motor, 4-cycle, 20-H. P., make and break spark, variable speed throttle governed, mechanically operated valves, speed from 150 to 500 R. P. M., weight no objection, motor to be used for a gasoline traction engine. will be transmitted to the driving wheels. The clutches and the pinions on the crank shaft to be so arranged as to remain stationary when the engine is standing still and delivering power with the belt. Fig. 2 is for the same purpose as Fig. 1, only the engine is a twin-cylinder with the cylinders placed a little distance apart, far enuf apart to allow the friction clutches and pinions to be placed on the shaft between the two cranks. Of course it will be harder to place the clutches and pinions on this shaft because it has one throw of the crank near each end. Cranks in both engines are 180 degrees apart. Engines to have a fly ball throttling governor, and so arranged that when the engine is throttled by hand the spark will be retarded or advanced as the case may be, and the speed to be varied from 150 to 500 R. P. M. At this speed do you think mechanically operated valves would give the best satisfaction? I have a small model of a traction truck that I think is almost perfect, and with your help hope to find a suitably designed engine. Any criticism will be cheerfully accepted, and all advice and suggestions from you will be greatly appreciated. Your articles in the "C. & A. Trade Journal" are very interesting and instructive.

W. I. BOWMAN.

Your device is not bad as far as it goes. The idea of a single lever for two speeds is not new, however. You will find it on most every auto to-day. For a traction engine better use a single cylinder light stationary engine without base. It is simpler and cheaper. If you think to save weight and vibration you must use two cylinders. Better buy a motor ready made and let it be of the opposed-cylinder type and you can get a better balance and use two fly-wheels with the clutches between the cranks and one of the wheels. Use suction operated inlets. They are simpler and will serve better at the speeds you expect to run. There are some advantages for high speed work in mechanically operated valves, but for the average man simplicity is worth more, and I believe future buyers will recognize this. C. E. D.

BEST FORM OF COMBUSTION CHAMBER AND ADVANTAGE OF OFFSET CYLINDERS.

Newark, N. J., June 30, 1907.

For the past year I have followed with interest, and to my great enlightment on various points, the numerous inquiries and answers found in your "Journal."

There are several points which I believe have not been taken up before in your columns that I wish you would make plain to me.

1st.—Which form of compression or combustion chamber is the most advantageous.:

A—The common oblong style; B—The semi-spherical; or C—The spherical?

2d.—Why do most engine builders off-set their crankshafts ⅜-inch or more from the centre line of the piston? It appears to me that they do this to give the engine a lead, if so. why not arrange the timing mechanism so the spark would be retarded. The results would be the same and the design more mechanically perfect.

3d.—Also, if an opposed four-cylinder, four-cycle motor could be arranged so that the opposite pistons could be directly connected and worked together with a common cross head, one connecting rod, and one crank-shaft-throw only, being necessary for every two cylinders, would the benefit of such an arrangement be enough to tempt one to make such a radical change from the standard style motor?

I know it would increase the life of the cylinders, pistons, and piston rings from 40 to 100 per cent., as it would do away with the rocking strain entirely, keep a more even strain on the piston, connecting rods and bearings and do away with considerable rack that most engines suffer from after running a while.—GEO. C. HOWARD.

The average theory deals with ideal conditions, and therefor does not fit working practice in many cases, and the theory is often very misleading, because actual conditions sometimes cannot even approximate theoretical conditions. The theory of the gas engine calls for the least possible cylinder wall in proportion to the quantity of explosive mixture. The theoretical best combustion chamber is the spherical one. It has been my practice to slightly concave both the cylinder and piston heads. These should not be hemi-spherical, however, for the movement of the piston prevents this shape being maintained. I prefer that they be cupt about equal to ¼ of a sphere and as the piston moves away the shape

for 1908

TOURIST MODEL, $1050

Same car equipt with two rear seats making light, stylish, 4 passenger touring car, lists at $1100.

This car is equipt with our Standard 4 cylinder, 16 H. P. air-cooled engine and the CAMERON patented system of transmission, 3 forward speeds, direct drive on each speed, 32 x 3 in. tires and full set lamps.

We will also manufacture our Standard Model 6, 2 passenger car with a number of 1908 improvements, listing at $850; and, with our greatly increased manufacturing facilities will be in a position to quote prompt deliveries.

We would be pleased to hear from live agents, who want an up-to-date line for 1908.

We will Exhibit at New York, October Show.

CAMERON CAR CO.

Digitized by Google

of the chamber becomes more nearly spheroidol during the early part of the stroke, but elongates beyond this in the latter part of the stroke. However, in vertical engines, concave pistons tend to gather oil which burns on and carbonizes.

Most engine builders do not offset their cylinders, but about two dozen prominent builders are using this improvement at present. It has been used on Duryea engines since 1897, and is correct practice and more mechanical than with the crank shaft on cylinder centers.

It should be evident that the working stroke needs all the advantage possible to get for it and that a slight angularity of the connecting rod, first one side and then the other, on the working stroke produces less friction than a large angularity on one side during the stroke. This lessened working angularity, is what saves power, permits a shorter connecting rod being used and therefor permits a lighter and more compact engine with consequently lighter weight and a lighter and a more comfortable vehicle. The off-setting has nothing to do with the valves or the spark, altho some slight effect may incidentally be produced by this off-setting, but is done so that on the working stroke there is less angularity of the connecting rod and more of the power is applied in turning the crank and less in side thrust against the piston wall. Of course the angularity of the connecting rod on the exhaust and compression strokes is much greater, but this is of little consequence, for the work done on these strokes is light.

In a horizontal or inclined motor a great angularity tends to lift the piston and overcome the effect of gravitation.

Your proposition to connect two cylinders to a single crank pin is a good one, altho not a new one. Engines are built using a 2-throw crankshaft with 2 or 3 cylinders to each crank-pin. This appeals to me as a much better design than the common system of 4 or 6 cylinders in a row. It permits a much more compact arrangement, shortens the crank-case, crank shaft and camshaft and lessens the total number of bearings. The only objection to such a design is, in my opinion, that the purchaser in his vulgar attempt to display the superiority of his pocketbook by the length of his motor bonnet, would be unable to do so if such a compact motor were used. I believe the future will see a much larger use of such motors, for the saving in weight, space and cost is considerable.—C. E. D.

THE HEDGELAND ANTI-SKID AXLE.

Webster Groves, Mo., July 28, 1907.

Will you please answer the following questions as I do not know where to get the information: How does Hedgeland's Anti-Skid Axle work? Does it drive by both wheels when turning a corner? Does it work by clutches, if so, what kind? What are its disadvantages? Any information you can give me will be gladly received. I am working on a differential myself.

W. F. SCHOENHARD, JR.

The Hedgeland Axle was a very ingenious device to drive the rear wheels without a balance gear. It served better than most devices of that kind which I have seen in the last 25 years, but we do not hear much of it now, and I fear it has gone to join its predecessors. It drove the inside wheel in turning a corner and this is its fault. It used screw actuated clutches and these gript the wheel hub when the axle was driven faster than the wheel. When the wheel ran faster than the axle it ran free of the clutch. You can find a copy of the patent in the Public Library at St. Louis and see its full construction and what the patent covers, and so learn what chance you have to make an improvement. If you can drive the outside wheel in turning and do it simpler and cheaper than the present balance gear you have a good thing. C. E. D.

FIRING ORDER OF SIX-CYLINDER MOTORS

Springfield, Mass., Aug. 6, 1907.

There seems to be a variety of orders in which the charges of six-cylinder motors can be fired. Will you kindly give some of the most common of these, and the particular advantage, if any, of each system? E. LOVELL SMITH.

I do not know how most makers do this, but the best arrangement is to make the six as tho they were two threes, but make one with a left-hand shaft and the other with a right-hand shaft. Then the two center pistons will move together, the two intermediate together and the two end ones together. Three opposed twos is also a good arrangement, but I do not think it balances quite so well. They can be fired in a variety of ways. Bend up a piece of wire and study it out for yourself. You will get both pleasure and profit thinking these things out for yourself. 1, 4, 2, 6, 3, 5 is a good order, but if you find a better one kindly send it to this department and give your reasons for thinking it so. C. E. D.

2 Cycle Engines

HUGH DOLNAR.

DALTON'S "FLYING PISTON" 2-CYCLE GAS ENGINE.

Will you kindly inform me if the enclosed sketch gives an idea that is practical? Also if the idea is new and of sufficient value to warrant a patent?

It contemplates the use of two pistons. A main or working piston and an auxiliary piston. To explain the action of engine, suppose both pistons to be at upper end of stroke, auxiliary piston seated against cylinder head, charge comprest by main piston.

When charge is ignited main piston makes the working stroke. At end of stroke piston uncovers exhaust ports. Auxiliary piston starts from head as soon as cylinder pressure falls below crank-box pressure, sweeping out burned gas and followed by fresh charge behind it.

On up stroke, just before completing compression, auxiliary piston passes cylinder recess allowing charge to pass below and piston to seat against head. Spark plug is placed in recess.

Auxiliary piston should not overheat. Only one side is exposed to flame. Other side is cooled by seating against water-cooled head, and by incoming charge.

A further consideration shows that this motor can draw in more charge than a four-cycle. In this engine charge is drawn into a space between cool side of piston and cold cylinder head. Charge is only slightly expanded by heat. Hence a greater volume of charge than with four-cycle where incoming charge is heated and expanded by contact with hot cylinder and piston heads and by mixture with burned gas in the clearance space.

The charge comes in one end and exhaust out the other, so that there is no change of direction of gas at induction. At high speed this is a pronounced advantage.

The cylinder head is not exposed to flame and therefore remains cold, permitting use of a stuffing box on auxiliary piston rod.

The spark-plug is placed in recess and is swept by fresh charge, preventing fouling. When engine is throttled down, the small charge is found in recess.

The mechanical construction is more complicated than the crank-case-compression two-cycle. Auxiliary piston can be very light and moved by as light mechanism as that required to lift an exhaust valve against cylinder pressure, for it only sweeps out exhaust. On compression stroke as both pistons (main and exhaust) move in same direction, the main piston crown will carry the auxiliary piston up, there will be no blow when they come in contact. DALTON.

The "flying piston" idea is old, and has been tried, and abandoned. The writer saw this en-

gine, constructed by a Mr. Joy, if memory serves, in Milwaukee, some four or five years since. The flying piston needs no mechanical action, as the crank-box pressure or other charge-pressure will force the flying piston down and the main piston lifts it up.

This scheme is bad, first, because it makes a motor which takes up too much room, and second, because of the great velocity of the flying piston in the scavenging and intake stroke.

There is no trouble with the burned residue in the 2-cycle working cylinder, and there is no need for any scavenging system, separate from the natural action of the 2-cycle motor.

The regular European practice for large 2-cycle motors, which are made double-acting

and as much as 8000 or 10,000 horse power each, is to use two supply cylinders, one for air and one for producer gas, with each working cylinder.

Extremely good results can, however, be obtained with crank-box pressure.

It is common to take the 2-cycle charge thru an automatic valve in the cylinder head. The "Wolverine" 2-cycle motors, Grand Rapids, Mich., use this plan.

A great number of "scavenging" 2-cycle motors have been designed, but the cylinder cleans itself so well as soon as the exhaust opens that none of the scavenging systems have come into much use for small 2-cycle motors.

Mr. Dalton's sketch is printed because it shows an idea which is now thought good by many persons not familiar with the history of the 2-cycle motor.—H. D.

INFORMATION ON TWO CYCLE ENGINES WANTED.

Boston, July 5, 1907.

Can you tell me of one or more books which will enable me to become conversant with the problems of successful gas engine construction and its theoretical and practical working out, especially with reference to the two-cycle type?

I would like to master the subject as completely as possible.

Can you tell me the name of the designer of the Elmore engine, or the name of some other expert on two-cycle auto engines whose experience would assure results as good as the Elmore gives?

If these questions come within the privilege of a subscriber to the C. & A. Trade Journal, I shall greatly appreciate your answers.

E. T. EASTON, M. D.

There is no book that will tell you what you want to know. Your only source of up-to-date information is the current Motor Press. The Journal is printing everything that offers, and gives more 2-cycle information than any other publication, at the present time.

The original Elmore motor was designed by Roberts, and gave not half the power now developed by the same sized Elmore engine. Roberts has published a book, "The Gas Engine Hand Book," which you can probably obtain of the Gas Engine Pub. Co., Goodall Building, Cincinnati, Ohio.

The large 2-cycle engine has been very thoroly worked out, but the final small 2-cycle motor has not yet been shown.

Harry Eason, 238th street and Matilda Ave., Bronx, New York City, has a 4-revolving-cylinder, 2-cycle motor which satisfies some of the conditions of the 2-cycle problem.

Perry Okey, Columbus, Ohio, has an excellent 3-stationary cylinder 2-cycle motor, which is the best 3-cylinder now built and at work, in the writer's opinion, and the "Atlas" auto motor, Springfield, Mass., is the best 2-cylinder, 2-cycle, small motor seen so far.

Note letter from N. C. Marks, in this issue. Detailed information as to the Marks motor will be printed in the Journal as soon as obtainable.

The basic principles of the gas engine are unchangeable, and have been formulated in many books. Perhaps as good a book as any for your purpose is "Gas Engine Design," by Charles Edward Lucke, D. Van Nostrand & Co., New York. The 2-cycle gas engine is apparently a bald impossibility from first to last. What man in his right mind would undertake to fill a cylinder with a combustible, light this combustible and do work with the heat generated, put the fire out and refill the cylinder with a fresh charge of highly combustible mixture without lighting the incoming charge, all in six one-hundredth parts of one second of time? Yet this is what a 2-cycle motor must do at 1000 R. P. M., and a 2-cycle motor has been shown which was strong at 2500 R. P. M. However, by continued experiments the writer expects to see this apparent impossibility, the 2-cycle engine, much simplified, greatly cheapened and improved. H. D.

A PERFECTED 2-CYCLE REVOLVING CYLINDER MOTOR.

San Diego, California.

In the June issue of the Automobile Trade Journal I noted the letter written to that paper by Mr. Harry Eason, in which he described a revolving cyclinder 2-cycle engine. I read your comments on Mr. Eason's rotating engine and was particularly interested in your description of what you consider will be the final car motor.

In the first place I am not a man of particular note, but I have followed the automobile and gas engine from the time of its first appearance in this part of the world. I am the designer and patentee of the California Motor Cycle, now being made in Toledo, Ohio, under the name of the Yale California. I had three years' experience manufacturing this motor cycle in San Francisco, and finally left that company to take a place as superintending engineer of the Howard Iron Works of this city, manufacturers of marine gas engines from 2 to 150 H. P. I am telling you this that you may judge of my experience and so you will not think that I have merely a fanciful idea of what I have done or can do in regard to the engine I am to speak of.

About a year ago I completed a revolving cylinder, air cooled 2-cycle engine: this machine is perfected and tested out thoroly in every respect. I do not use crank box pressure for supplying the cylinders, neither do I scavenge the cylinder, but I can use any charge volume desired as well as clear the cylinders of the burnt gas. This engine can be made with 1, 2, 3, 4 or 5 2-cycle cylinders, or as many as is possible to locate about a single crank shaft. By actual brake test I

NAILS CANNOT PUNCTURE

WOODWORTH

ADJUSTABLE TREADS DETACHABLE

Tested with Six-Penny Nails

Woodworth Treads are all and more than you represent them to be. I would rather have my auto in the shape the tires are in now with Woodworth Treads on them than when new and without Woodworth Treads. The tires cannot now be punctured. I have tested them thoroughly by driving six-penny nails through boards and running the wheels over them back and forth. They stood the racket without a sign of a puncture. J. J. MICHLEY, Wilson, Kan.

Woodworth Tread for 1908: The above extraordinary testimonial refers to the Woodworth Tread as made heretofore. For 1908 the Woodworth Tread is made of three thicknesses of chrome leather full across through which closely set rivets with hat-shaped heads are carried, turned and clinched. The area of leather protected by these rivets is very much greater and the mileage of the Tread is increased at least 50 per cent. A more durable and convenient buckle and strap are used than formerly, and the whole construction is greatly improved to give to the tire far greater protection and to the Tread even more lasting qualities.

The Special Woodworth Tread: For Rutty Roads: This is made as above but with the addition of broad oval-headed steel rivets set close together along the sides to protect the leather from wear in ruts or on very rough roads.

Write today for booklet, "Safe and Sane Automobiling." Regular sizes and prices are as follows :

get the same power out of my revolving cylinder 2-cycle engine at 500 revolutions as would be developed at 1500 revolutions by a 4-cycle engine same bore and stroke of the ordinary design. I claim by careful figuring that my rotating engine can be manufactured and placed in a rig for one-third the cost of any stationary cylinder engine on the market, and can be kept in repair and running order for one-fourth the price. I will close by saying that my greatest desire is to see my revolving cylinder motor on the market before long and that it may become of sufficient importance to repay me for my four years of study and patience to get it where it is. At present my whole attention is taken up with my patents, but I have every prospect of placing my machine before the public at an early date.

R. C. MARKS,
Supt. Howard Iron Works.

The Journal will be pleased to print a detailed description of the Marks motor as soon as it can be had for publication. Without question, a revolving cylinder 2-cycle motor can be built for one-fifth of the labor cost of a 4-cycle motor, ordinary form, to give same horse power, with a reduction in weight of from 40 to 60 per cent. as compared with the 4-cycle, and the 2-cycle repairs are confined to the piston rings and rod and crankshaft bearings.

Mr. Marks asserts that he can now show what the writer is certain he himself will show, at some future time, that the 2-cycle revolving cylinder gas engine is the final car-motor.

H. D.

AN AIR-COOLED TWO-CYCLE ENGINE DESIGN.

I send you enclosed a blue print of the cylinder drawing for a two-cycle engine I have designed, and which is laid out, as near as possible, in accordance with suggestions by Mr. Malcolm and Mr. Dolnar.

I should be pleased to have Mr. Dolnar examine this print and make any criticisms he sees fit.

You are at liberty to use this print in any way that you desire, as I believe that an interchange of ideas will help solve the two-cycle question, in which many people, including myself, are deeply interested.

H. E. BURLINGAME.

While this cylinder shows nothing new, it is all good, and the drawings are well made and will interest many 2-cycle artists. The thing now wanted is the very best and lowest cost 3-cylinder 2-cycle motor, unlimited charge volume and compression, air-cooled.

Mr. Burlingame will confer a favor by reporting performance of this cylinder, together with fan particulars, if any fan is used for cooling. Would like to print H. P. developed, maximum R. P. M., and fuel consumption.

H. D.

MANVILLE'S 2-CYCLE DUAL-UNIT CYLINDER.

Carbondale, Penn.

Mr. Manville submits a well executed drawing of a dual unit 2-cycle cylinder, water-cooled, which is well proportioned save that the port-bridges are smaller section than seems wise. Mr. Manville says:

"I am enclosing to you, under separate cover, drawings of a cylinder casting and piston, for use in a motor of the two-cycle type having admission through a slotted disk in the crank-case. By examining and criticising the design of these parts and by acquainting me with the result, you will place me under great obligation to you."

K. R. MANVILLE.

The port-bridges, four of them on the intake side, are only ⅛-inch wide. The writer much prefers the exhaust and intake ports in different planes, as shown in the "Atlas" motor, with a central intake thru the piston head. In this "Atlas" form the ports are large, and have no bridges and the intake and exhaust are symmetrical.

The writer does not view the dual unit 2-cycle cylinder with favor, altho he does regard the triple-unit 2-cycle cylinder as the best form for the small 2-cycle crank and connecting rod gas engine, and believes that if a 2-cycle motor has more than one cylinder, it shall have three cylinders, and no more. The 3-cylinder, 2-cycle is the equivalent in effect on the crank-shaft of the 6-cylinder, 4-cycle motor, and turns its shaft well enough for car-driving in the crank and connecting rod form, or can be made to give six impulses per revolution to a straight shaft without cranks or connecting rods. In view of these facts the writer does not commend the dual unit 2-cycle cylinder casting.

A NOVEL 2-CYCLE DESIGN

Mr. W. G. Henderson, who gives 10723 Olivet avenue, Cleveland, as his address, will kindly pardon Hugh Dolnar for mislaying his interesting communication. Mr. Henderson writes as follows:

I have always been of the opinion that the main issue in the two-cycle motor was the simplicity and low cost of construction, and keeping these ideas in mind, I aimed to overcome some of the present troubles in the two-cycle motor, namely—premature ignition, low crank case compression, time lost in charging cylinder, and consequent poor results. In the design shown when the piston reaches the top of the stroke, a few small holes drilled near the top of the small cylinder, as shown, admit air to the piston inside and the crank box, and when the piston reaches the bottom of the stroke, this pure cold air is the first to come in contact with the burned gases, thus preventing back firing.

The crank case compression is also improved. The design of the piston admits placing the wrist pin near the head of the piston, and lengthens the rod, and keeps it cool. It will be readily seen that because of the small end of the piston passing into the cylinder, the piston displacement in the crank case is greater than that in the cylinder, which, while reducing the piston area somewhat, increases the relative volume of the mixture in the crank case. In regard to charging the cylinder the particular advantage gained here is that as the old charge is released at the bottom the new charge is already entering at the top and shoots directly downward. The exhaust port could be open at all sides of the cylinder if necesary. There appears to be less chance of the new charge mixing with the old charge in this design on account of the fresh gas closing down on all sides of the cylinder with the small piston in the center. Hoping to hear from you in

1908 Austin Models

6 Cylinder Austin, 90 H. P.

6 Cylinder Austin, 90 H. P.

The 1908 Austin Models are designed to exactly meet my own personal requirements after 6 years of building high grade cars, and to fulfill the ideas of that class of owners who want the "sportiest" kind of a car it is possible to get with *all* the power and speed they can possibly use—a car that is either a touring car or a runabout capable of making a 1000 mile trip any time, and will beat anything on the road.

Our 6 cylinder 90 h. p. model is my idea of such a car—and I believe it stands today without an equal in the Automobile world at any price.

Our new combination body as a touring car has an extra folding footboard chauffeur's seat. The tonneau seat can be replaced in 3 minutes by a rumble seat, thus converting the car into a runabout of the very latest design.

The equipment is complete in every respect, and includes both seats, and extension surrey top for the touring car, and single top for the runabout. We also furnish this new combination body on our regular 60 h. p. model in place of 7 passenger touring body. This regular standard body, either with or without detachable limousine top will be furnished on both 60 and 90 h. p. models.

All Austin cars have the celebrated Austin Motor and are built in our own shops under my personal supervision.

Send for Catalogue and detailed information about our new models.

the questions and answers column, I am
W. G. HENDERSON.

ACTION OF HENDERSON'S 2-CYCLE MOTOR

The pure air ports at the top of the small cylinder should have as much area as may be. When these pure air ports open the crank-box intake port has been opened for a considerable time, and the mixture fills the crank-box at a little below atmosphere. As soon as the pure air ports open the crank-box is filled with mixture and pure air up to atmospheric pressure. The top, pure air, ports close before the crank-box intake port closes, so that the action of the motor in the working stroke is the same as if the top cylinder and the upward prolongation of the piston were not present, save for the reduction of the working piston area, which is but small. The exhaust port can well be very short up and down, as it can be carried all round the cylinder, with bridges enough for strength.

This Henderson design is the "Atlas" design carled to the limit, and has very decided advantages both in action and in durability, besides giving the longest possible connecting rod and the best possible piston and rod cooling. The cylinder charging is much improved, and the cylinder charge volume can be made as great as is desired. The only drawback is the increased motor height and the slightly added cost of the second piston finishing. This engine will probably give more power for the same piston diameter than the ordinary 2-cycle form, because of better charging and better charge placing in the cylinder and crank-case firing appears to be made impossible. Not only is the piston rod length increased, but the piston bearing in the cylinder is greatly extended, and this motor should be far more durable than the ordinary 2-cycle.

So far as the writer is aware this Henderson 2-cycle motor is new, and can be covered by a good patent; it certainly appears to be a better design than previously seen. It is possible, of course, that this design is not new; if old, probably some reader of the Journal can tell where it was previously shown. The design is certainly good.—H. D.

Makeshift Battery Repairs

In using dry batteries, the motorist as a rule has little or no trouble from the time they are installed until the time they are "run out," at which time there is a possibility of stimulating them for a short time by boring a hole in the wax and then putting in a little water, vinegar or muriatic acid.

Occasionally, however, it happens that one of the posts is broken off, so that there is nothing to which to attach the terminal wires.

In case the broken terminal is a negative one, it can be repaired by boring a small hole in the side of the zinc casing, inserting the wire and twisting it tightly so there is no chance for it to jar loose. When it happens that it is the positive terminal which goes wrong, it is generally possible to notch the carbon all around or bore a hole thru it. Should the pole be broken off too near the wax, a common wire nail may be driven thru the wax into the carbon, care being taken not to split the wax, nor break the carbon. The nail should just touch the carbon and be left protruding far enough so that the wire can be twisted securely about it and thus complete the connection.

A storage battery will lose its strength if left for any long period of time. If it is desired to put a battery away, and still retain the charge, the plates should be removed from the liquid and hung up in a cool, dry place. They will then suffer no deterioration, no matter how long they be left unused.

A Car Possessing all the Elements of True Greatness:—

Wayne

THIRTY FOR 1908

$2500.00 F. O. B. Factory—"Nothing to buy but the license."

WAYNE Thirty for 1908 will not ask your consideration—it will force its extraordinary excellence upon you. One or two of the foremost cars at an approximate or higher price will suggest themselves as worthy of comparison with the new Wayne at $2500—but none of them, in operation, can possibly give an equal demonstration of actual value.

All the facilities of the great new plant centred upon the perfection of one model—and that one model sold complete with top, storm front, side curtains and emergency seat in tonneau.

1908 Wayne Thirty Ready for Delivery.

Difficulties Successfully Overcome by Users

Under the above heading we will be pleased to publish how *you* solved *your* automobile difficulties. Many troubles have been successfully overcome by means of the answers in these columns. We earnestly urge those who have been thus benefited or any who have overcome such difficulties to send a brief account of the same to the Editorial Department of the Cycle and Automobile Trade Journal.

TROUBLE WITH PILOT LIGHT.

Woonsocket, R. I.

E. P. R. desires to hear my experience with pilot light. I have not had much trouble with my pilot light, but more with the main fire. Before each run I take the cleaning stem out and smooth it with fine emery cloth, not overlooking the float sides at the end of the cleaning stem. I clean the pilot vaporizer with gasoline, putting in about a teaspoonful at a time, and blow it out with the breath, blowing in at the union end C and covering holes E and F. I then put in the cleaning stem, turning it around and sliding it in and out, to dislodge the carbon, then I blow the gasoline thru as before. Remove the cleaning stem, wrap the vaporizer and let the carbon out. Assemble and blow gasoline thru again, at the same time slide the cleaning stem back and forth until a straight stream of gasoline flows thru. Sometimes I connect the line at the union C with the pilot vaporizer out of the burner, then open valve A and let the kerosene on to show if it is all clear. The pipe from the union C to needle valve A is a small annealed tubing. The test D should be the proper distance from the end of the vaporizer. With my 16-in. burner it is 8⅞ ins. When I put the pilot light out with valve A I immediately close the needle drip valve B so the oil will not be in the vaporizer when it is cooling, as it is said to carbonize and make trouble later. For the most of two seasons I was troubled with the roaring noise of the burner, which could be heard half a mile. I was told to hit the bottom with a hammer; that did

not stop it but for a few minutes; they said it was the vibration of the bottom. I tried lower pressure on the oil, but after a while it stopt of its own accord. At the Boston Auto Show they claimed to have found a remedy: to drive pieces of sheet steel 3-16 wide into every other slot down flush with top of burner casting. I put in seven or eight pieces of galvanized iron in the place where the sound seemed to come from; It has seldom made any noise since, but I cannot say how much good the galvanized iron pieces did. It seems to me with a certain pressure on the oil, with a certain mixture of air and vapor, it will roar or whistle. I have 125 lbs. on the oil, and am going to try 150 lbs. I have been troubled considerably by the clogging of the main vaporizer pipes, first by a brown gummy substance, then by carbon, in my new vaporizer. I took the elbows off and once found the close nipple filled with this deposit; again found some in the elbow and in the pipe. After a run I took off the elbows again, ran a wire into the vaporizer pipes, pumped up the auxiliary tank to 125 lbs., then quickly opened the valve; the oil flowed from each line moderately, then the oil suddenly flew out 4 or 5 feet. When I first went out the pilot light did not work right, the flames shooting up 2 ins. or more. The flame should be blue, blending into a cherry red, with no light or yellowish flame. When I fired up the second time I had steam to spare. Have been thinking of putting tees in place of the elbows on the vaporizer, if I find they will not leak around the plugs, so by removing the plugs I can clear the line without taking the connections off.—C. S. LAWTON.

CURING AN ERRATIC MOTOR.

Upon one occasion the writer was called upon to drive a 4-cylinder air-cooled car several hundred miles just after it had been in rather inexperienced hands. The engine was cranked and ran idly throttled down and seemed to be all right, but as soon as the throttle was opened the engine would speed up for a short time and then gradually slow down and almost stop. After running very slowly for a short time it would speed up again, the throttle all the time remaining unchanged. This slowing down and speeding up again was almost periodic in its recurrence.

An investigation of the carburetor disclosed nothing out of the ordinary. Following the gasoline pipe line back, however, to the tank under the front seat it was discovered that just below the tank the small copper gasoline feed pipe had almost two full twists in it and looked like a corkscrew. Some novice in endeavoring to stop a leak at the connection of the tank had continued turning the connection after it had seated, with the result that the pipe was twisting and offering just sufficient resistance to give the impression that the connection was being tightened. The opening thru the pipe was thus restricted to such a small area that the gasoline flow was sufficient to keep the motor running slowly, but on an opened throttle the supply in the carburetor was quickly exhausted and the engine almost stopped until the gasoline level again raised in the carburetor.

After this discovery it was but a few minutes' work to cut off the pipe and solder on a connecting sleeve, as it was found impossible to sufficiently open up the pipe by untwisting it. After this was completed the engine ran perfectly and the start was made.—S. F.

NEVER SAY "GET A HORSE."

There are probably very few automobilists who have not at some time in their experience been accosted by the wayside urchin with "Get a horse." Unfortunately the writer found himself in this predicament one hot Sunday afternoon when an unusual feeling of the steering wheel indicated something wrong with the steering gear. Upon investigation it was found that the right front wheel was just ready to fall off, the peculiar feature being the fact that altho the outer cone, ball cup and all the balls were either ground to bits or lost, not the faintest squeak had given warning of the precarious state of affairs. This was probably due to the fact that the dust cap and bearing were packed solid with grease, which, melting from the heat, had thoroly lubricated the bearing while the grinding process had been going on.

A closer investigation showed that the threads were so mutilated that altho an extra cone and a few balls were found in the "scrap box," they could not be used—anyway, there were no traces for the balls to run in.

Fortunately we were only twelve miles from home, but a survey of the neighborhood showed nothing more hopeful than a drug store. Here we purchased a bottle of vaseline in lieu of grease. The end of the axle we then wrapt with all the available string, straps, cord and wire to be found, care being taken to wind it so the rotation of the wheel would keep it tight. This was then well covered with the vaseline, and thus a crude bearing was formed for the

inner surface of the wheel hub to run upon. As it was impossible to screw a retaining nut onto the mutilated thread, and it was found that even if this could have been done, the wheel could come off, as without the ball cup the hole in the hub was larger than the diameter of the nut, other means of retaining the wheel in place had to be devised. A very large washer was found and placed over the axle end and against the string, wire, etc., to keep it in place. This washer bore against the wheel hub. In order to hold it in place a nut was slipt on the axle outside it, and the end of the axle riveted over the nut to hold it in place, so it was impossible for the wheel to come off.

The return trip was made very slowly and altho the wheel wobbled badly we reached home without having to "get a horse."—F. S. E.

USEFUL KINKS.

Marshall, Minn.

My excuse for describing the two automobile conveniences in this article is that nothing can be purchased in the market in their line which will equal them in usefulness.

A common snap clip intended to hold the wire terminal to the spark plug in my runabout proved very annoying by frequently shaking loose. Securing a piece of spring brass about one-twentieth inch thick, five-eighths inch wide, and one and one-fourth inches long, I bent it in the middle until the ends came together. When released the ends sprang apart one-fourth inch, and in the angle of this "V" shaped piece I soldered a short piece of number sixteen copper wire to guard

AUTOMOBILE TRADE JOURNAL

against it breaking at the bend when in use. I then drilled a three-sixteenth inch hole through the ends three-eighths inch back, and placed it on the spark plug pin, under the thumb screw. When the thumb nut was screwed down the plates came together, clamping the terminal wire firmly, as shown in the sketch, yet capable of instant release by simply turning the thumb nut back one or two turns. There is no possibility of shaking loose, or breaking, or necessity of turning an eye in the end of the wire, and it will clamp various sized wires or a group of small wires. It makes an equally good battery connection, requiring nothing but plain wire to connect the cells. The material of which it was made was thin "brass rule" obtained at a printing office.

A HOME MADE SPRAG.

On my way up a long hill on slow gear my chain broke, and if I had not been favored by a chance to let my car back against a convenient side bank, I should have been in a very dangerous situation, for the hub brakes could not be depended upon to hold the car. Upon ariving home I at once had made the following sprag brake, and its use has been the source of an agreeable safe feeling every time that I have climbd a hill since. A piece of half inch round steel rod thirty inches long was bent at one end at a right angle four inches long, and eight inches of the other end was bent back upon itself and welded there to give extra strength. This end was made pointed, and a five-sixteenth inch hole was punched through, four and one-half inches from the point. A piece of hickory, two inches square and three and three-fourths inches long, was bored through lengthwise with a nine-sixteenth inch bit. The four inch end of the sprag was placed in this hole and retained by riveting a washer over the end of the rod. The wood was hol-

AUTOMOBILE TRADE JOURNAL

lowed out a little on one side to make it fit, and then clamped tightly to the back side of the front axle by two ordinary carriage axle clips with cross ties as shown in the drawing. A piece of trace chain was fastened by a small clevis to the sprag in the hole near the point, and the other end was attached to a cross piece of the chassis frame, the length of the chain being arranged to allow the sprag to drop almost perpendicularly from its axle attachment. A half inch wide lace leather strap fastened to the third link of the chain from the sprag and long enough to permit the sprag dropping free, passed up through the car floor to a screw eye on the dash. A screw hook farther up on the dash served to hold the strap when the sprag was drawn up underneath the car. This sprag is conveniently located, easily put in action, will not permit the front wheels to skid around, and is entirely out of sight when not in use. In ascending a hill where there is any possibility of a backing accident I allow the sprag to drag as a precaution. This is not only the most effective sprag brake that I have ever seen, but it is inexpensive and easily applied.

The 1908 MITCHELL

at all agencies

September 1, 1907

The 1908 Mitchell, the finest touring car in the world for $2000 as well as the runabout and the NEW Mitchell Roadster shown at all agencies September 1, 1907. See them. Say to any Mitchell agent—"Show Me." He'll show you in a Mitchell for 5 miles or 50 whichever you say. Convince yourself that for power, control, silence, speed and sweet running there is nothing can equal the 1908 Mitchell at the price.

The 1907 Mitchell a Winner

At Hamline Track, St. Paul, Ed Zerbies in the 24 hour race, after wrecking two cars on the fence at the turns because of the dust—having no other car, borrowed a 20 h.p. Mitchell Runabout from a doctor in the crowd and drove it for nearly four hundred miles until another Mitchell 35 h. p. could be secured. In the face of this awful handicap Zerbies finished only 28 miles behind the winner who drove a 40 h. p. car, selling for over twice as much as the Mitchell, and in addition broke all previous world's records for 24 hours—183 miles.

The 1908 Mitchell chassis is a refinement of the 1907 with all the latter's good points and the same standard construction. You can't afford to overlook the 1908 Mitchell.

The Jones on

Locomobile ·40·

On all the Best Cars you will find the

Jones Speedometer

And here's a reason or two:

The Jones is the *pioneer speed indicator.*

The Jones is the accepted *standard* speed indicator.

The Jones is used in this country and abroad by the police departments as a means for timing motor vehicles for reason of its accuracy.

The Jones won the Gold Medal *Reliability* award in the Royal Automobile Club's Contest. All American and Foreign manufactured speed indicators sufficiently practical to enter, were in this Contest.

S. F. Edge had the Jones on his Napier Cars when he made the World's most remarkable record, traveling 1,588 miles, 1,310 yards in 24 hours; averaging 66 miles per hour, on the Brooklands Track, London, England.

The Speedometer cable revolutions per hour at a 66 mile speed total 168,300 or 4,039,200 in 24 hours, demonstrating the Jones "*staying*" qualities.

Compare this to what other indicators have done—then you'll specify the JONES for your 1908 car.

Jones Speedometer

ents very simple. The pinion shaft is ted with two sets of Timken bearings, pering different ways. The spring seats e of the oscillating pattern, and cannot ove sideways, but permit of a slight ovement around the axle, which means at no strain is placed on the springs hen the power is applied, all the strain ing taken by the torsion rods. The rear le tubing is 2½ inches in diameter with inch wall, keyed and riveted into the using. A truss rod runs from the side ring blocks under the center of the differential housing.

The front axle is "I" beam section rged in one piece from chrome nickel eel. The steering knuckles are fitted th roller bearings.

WHEELS.

The wheels are 34 inches in diameter, ont and rear, have 1½-inch second owth hickory spokes, and are fitted with ick detachable rims to take any standd make of American tire. The front es are 34x4, and the rear tires 34x4½.

and also operates against metal.

FRAME AND SPRINGS.

The frame is made of nickel steel, ch nel section, with a sub-frame to carry t transmission. The front is narrowed t inches on each side, giving a large rad of action for the front wheels in turni The front springs are semi-elliptic, ribb and banded, 41 inches long by 2¼ incl wide, connected direct at the front a suspended by plates at the rear. The r springs are platform of the three-po suspension type, consisting of two se elliptic springs hung outside of the fra 43½ inches long, and a cross spri shackled at their forward ends and bol to a cross member of the frame.

The mud guards are of the flaring ty made from prest steel; the front o are fitted with mud shields on the ins next to the hood, connected to the m side member of the frame and fitted the running board at the rear. The r ones are of extra length, extending p the body, keeping the mud under all c

Fig. 4. 1908 Pullman Model 4-40 Runabout. Practically the same chassis as Models I a , except it has only a three speed selective sliding gear, 108-inch wheel base. The car weig bout 2400 pounds, and is claimed to do 60 miles per hour. Price complete, $3000.

STEERING GEAR AND CONTROL.

The steering gear is of the screw type ted with a ball bearing cone to take up y lost motion which may occur. It is ounted on the aluminum crank case, d is suspended by a bearing on the sh. The spark and throttle levers are rried on top of the steering wheel, but not move with it. They operate ru gears located at the bottom of e housing, and connected to the vertical aft to which are connected the levers

ditions from the back of the rear s and are connected at the front end to running board. The running boards of seasoned wood covered with linole with brass bindings, and fitted on right with a waterproof tool box, and the left with a waterproof battery b The dash is an aluminum casting cur on the top and sides, which gives pro tion to the coil and dash equipment. is made with a bracket which bolts di to the frame and supports it rigidly.

Hosted by Google

copper, with compartments to prevent splashing, has a capacity of 18 gallons, and is located under the front seat.

BODIES.

The bodies are made in their own factory from the finest selected woods. The bendings are one piece. The tonneau seat is 55 inches wide, giving ample room for three to sit comfortably without crowding. The doors are 21 inches wide, and fitted with positive double-acting lock and double heavy one piece bronze hinges. The front seats are of the individual type, upholstered with the best grades of hand buffed, bright finished leather, upon a foundation of springs and curled hair. Each car is equipt with a full set of tools —jack, pump and repair kit—two gas lamps, two oil lamps, and one tail lamp. The price of Model I is $3250.

MODEL J.

Model J is a 40 H. P., seven-passenger car, the chassis being identical with the Model I, with the exception that the motor is equipt with a double system of ignition, consisting of the standard high tension system of storage batteries and dry cells, and in addition a magneto. A double set of plugs is employed, each located over the intake valve and port, and so arranged that both systems may be used separately or together, as described. The body has an unusually large tonneau with two comfortable extra folding and revolving seats, and the car has, in addition to its ordinary equipment, a lined cape top with side curtains and a folding glass front. The price complete is $3750. The colors of Models I and J are carmine body, light red gear, red leather, or dark blue trimming to order.

4-40 RUNABOUT.

The Model 4-40 Runabout is practically of the same specifications as the Models I and J, except that it is fitted with a three speed selective sliding gear transmission, 108 inch wheel base, and with a magneto as regular equipment. The motor, frame, axles, etc., being practically the same, only lighter. The weight is about 2400 pounds, and it is claimed the car will develop a speed of over 60 miles per hour. It sells for $3000.

6-30 RUNABOUT.

The Model 6-30 Runabout is a light roadster or speed car, with six cylinders of smaller dimensions, developing 30 H. P. at 1000 revolutions per minute. A magneto is furnished as regular equipment. The specifications are practically the same as the 4-40, except the parts are lighter and the wheel base is 104 inches. It weighs about 1900 pounds, and is said also to be capable of making a speed of over 60 miles per hour. The price is $2750.

Brush Patents on the Market

Several patent rights on the inventions of Alanson P. Brush, of Bates and Congress streets, Detroit, Mich., are now on the market, the licenses held under these patents by a prominent automobile manufacturer expiring October 1. These patents include those covering the planetary transmission, automatic carburetor, multicylinder oiling system, copper water jacketing, variable inlet control, bevel gear rear axle transmission, etc., used in a very successful make of car for several years, and the efficiency of these designs are beyond question.

Mr. Brush invites correspondence with automobile and parts manufacturers who might desire to manufacture under these valuable patents.

The Name "Knox" Belongs to Auto Company

Chief Justice John A. Aiken, of the Superior Court at Springfield, Mass., filed a decision in favor of the Knox Automobile Co. in the case of the Knox Automobile Company against the Knox Motor Truck Company, both of that city. The case arose over the use of the word "Knox," which was used by both firms, owing to the active connection of Harry A. Knox with each, and the decision just filed enjoins the motor company from further use of the name in its corporate name, in advertising its products or on its trucks. An injunction to this effect is granted but Mr. Knox, as a member of the truck company, personally is not forbidden to use his name so as to show that he is connected with the company, so long as this is done properly and in good faith. The case has been pending for a long time, the automobile company having brought its bill of equity two years ago.

Cheap Traveling

Those who labor under the impression that traveling by automobile is an expensive proposition will be interested in the list of expenditures compiled by D. E. Levy, the New York broker, which, he claims, cover his recent 3000-mile tour to Chicago and return. Mr. Levy drove his Matheson car and was accompanied by a party of five. The expenses for the 3000-mile trip were as follows:

Gasoline, $51.39; oil, $12.40: storage, $13; washing, $12; polishers, $4.25; kerosene, $0.75—total, $93.79.

The total of $93.79 figures out three cents a mile or five mills per mile for each passenger. In comparison railroad travel is not only very much more expensive, but lacks the advantage of complete independence enjoyed with automobile travel.

e Payne-Modern is a new line of cars, ving a great number of novel and high-genious features, brought out by the ern Tool Company, of Erie, Pa., U. S. nanufacturers of screw machine equip-t, including chucks and self-opening for cutting threads.

is concern interested itself in the nanical problems of the motor car in placed its investigations and exper-ts in the hands of a well qualified and oly experienced automobile expert, has ever since pursued a costly course tudy and experiment, resulting in the uction of three different chassis models, ur cylinder, five passenger touring car, cylinder two, three or four passenger ster, and a six cylinder five passenger ing car.

ese Payne-Modern cars are here shown specifications, while the six cylinder ing car and its motor are now first n and described in some detail.

e Payne-Modern motor car study was expanding steel rings and steel balls which act as keys and when driven home hold the copper fins so firmly that they can be removed only by breaking up the cylin-der. The gear-shift is of equal originality and mechanical exactitude and is also patented, and also depends for its working on a novel use of steel balls. Both the designing and the construction are beyond criticism so far as form, perfection of work-manship and certainty of action are con-cerned.

The five passenger six cylinder touring car has a wheel base of 118 inches and 56 gage. The motor is air cooled, 4 cycle 4 by 4½ inches, with 80 lbs. compression which is extremely high for an air cooled motor. This motor develops 36 H. P. at 800 r. p. m. Completely equipt, tanks full, with some heavy robes in the seat and chains on the rear wheels, the scale weight of one of these cars was 2840 lbs. The price is $4000.00, including 5 lamps, mats, horn, tools, gas tank, cape top and

Fig. 1. The Payne-Modern 5-passenger, 6-cylinder, touring car. Wheel base, 118 inches; ge, 56 inches; all four tires, 34 inches by 4 inches; motor, six, air-cooled, 4 cycle, 4x4½-h cylinders, compression 80 pounds, showing 36 H. P. at 800 R. P. M., which drive the car miles per hour. This car, fully loaded, can easily make 65 miles per hour on a good road. nks full, completely equipt the car weighs 2840 pounds; price, including 5 lamps, mats, horn, ls, gas tank, cape top, and speedometer, $4000.

n with fixed convictions in favor of ooled motor cylinders, the use of a liar patented ball-clutch device for ge gears engagement selection and an nal analysis of vehicle spring action, h resulted in the diagonal placing of elliptic springs which is a unique lty that first challenges criticism in Payne-Modern motor models.

speedometer, completely equipt for ex-tended touring.

The five passenger four cylinder touring car has a wheel base of 100 inches, and 34 by 4 inch tires. The four cylinder motor shows 24 B. H. P. at 800 r. p. m., fully loaded. This car can make about 45 miles on a good road. The weight, with tanks full and complete equipment is 2100 lbs. The price $2800.00 includes the same con-

Hosted by Google

bout 55 miles per hour at 1000 r. p. m. is expected to weigh about 2000 lbs., and make 75 miles an hour on good roads, nd will be fitted with a body to seat two, ree or four passengers. The price will e $3600.00, with complete equipment.

NOTABLE FEATURES.

The first thing noticed in looking at a ayne-Modern car is the oblique placing the half-elliptic springs, which are tilted in front by curving the frame-side neck ward instead of downward, while the ear spring-end is linked to a long down-anger fixt to the chassis frame. This stonishing variation from all previous ractise was made to take advantage of e following conditions, well known to be separable from wheel carriages of loads:

(a) A wheel pivoted on a pendulum can e pushed past a vertical road obstacle of ny height below that of the pendulum sus-ension point.

(b) A wheel pivoted to a horizontal ember in the line of the wheel axis and aving a vertical lift, can pass no vertical oad obstacle of more than one-half the heel diameter under any conditions, and nder the conditions of ordinary wheeled arriage practise the wheel, which must se in a perpendicular line against spring ction, can pass road vertical obstacles of nly a very limited height, considerably ess than one-fourth of the wheel diameter.

(c) A pendulum-carried wheel can sup-ort a vertical load on a spring equally as more than half the wheel diameter height, and cannot well be made to mount vertical obstructions of a hei greater than one-fourth of the wheel dia ter, and as it is desirable that motor wheels, pushed, pulled or turned by pow should pass the highest possible road stacles with the least possible power penditure and probability of damage, Payne-Modern car designers assumed t by giving the wheel-carrying spring so angle between the vertical, and the h zontal, advantages could be had.

Experiments were made by placing spring at different inclinations, alw with the front end of the spring eleva and the most favorable spring inclinat angle, all conditions considered, was fo to be about 15 degrees from the horizon

The resultant action is too complex be fully analyzed here, but the pract result obtained is that which would c from considerably increasing the w diameter and at the same time largely ducing the load. The wheel is given m more time in which to surmount a obstacle of given height and the sp also yields the more readily, this s spring inclination making the most prising difference in the riding of the

t retained, so that the valve action ngths can be instantly adjusted to any sired clearance. The cams are machine eel, case-hardened and applied to a 7/8 dia. cam shaft with Woodruff key and n retention for each. The whole valve ge and valve action assembly is so de-gned and retained as to permit extremely ick and convenient assembling, dis-sembling and the most delicate adjust-ent. The intake and exhaust assemblies e the same, save for cooling fins on the haust valve cage.

Beginning in front, the order of cylinder ing is 1-3-2-4-5-6, adopted after many ials of other sequences.

throttle and air intake valves, butter type, linked together so as to incre the air supply as the throttle is ope and diminish the air supply as the thro is closed. The carburettor delivery p is horizontal from the carburettor pla high up in the rear of the motor, and bent upward into the distributing chamb located between the cylinders as sho in the plan view of the motor. As f applied the two forward cylinders rob the other four of fuel, but by exten experiments with the bent up carburet pipe admission to the distributing ch ber, shapes and dimensions were fo

Fig. 5. Payne-Modern Six. Plan of motor, showing exhaust pipes on both outsides of mot nd the "turtle" mixture chamber between the two banks of cylinders, from which 6 inta ipes lead to the six cylinders; all intakes are in the middle of the motor, between the cyli ers.

The pistons, piston pins, rods and cylin-ers are ordinary construction; cylinders, istons, rings and crank-shaft all ground.

THE COOLING SYSTEM.

The applied copper fins now used, see lustrations, half-tone and construction rawing reproduction, consist of two, milar, sheet-copper, corrugated fin-halves, ipped into fin-seats ½-inch diam. by 3-16 ches deep, bored in the 3/8-thick cylinder alls, then split rings dropt in be-ween the fin-halves in their cylinder seats nd finally 5-16 steel balls are driven in e rings to expand them powerfully and retain this four-piece cooling fin assem-ly firmly in place. The cooling is efficient, ut the cylinders are costly, as each ylinder has 252 cooling-fin seats accurate-finished, 504 cooling-fin halves, copper,

which give each one of the six cylin so nearly the same fuel supply that exhaust rhythm is perfect.

The wheels and axles are Timk front and rear, regular forms, and no detailed description.

THE INCLINED SPRINGS.

The springs are placed at angles about 15 deg. to the horizon, and are elliptics. The spring eyes take plain b without special bushes and without sp oilers. The front springs are 40-in long by 1¾-inches wide, 7 leaves. rear springs are 42-inches long by inches wide, 7 leaves. All leaves tongued and grooved, and no bands used. The 15 deg. angle placing seem do away with nearly the whole of sp

peed. The gearing is all steel, 8 d. p. The peculiarity of this gear lies in the neans used for clutching the gears, all of vhich are normally loose on the line shaft nd side shaft, each pair in mesh and all tanding still no matter what the line and ide shafts are doing, this being direct lrive conditions.

The gear selection is made by moving steel balls, which normally engage the ide and line shafts only, but are free to nove in slots in the line and side shafts valls so as to engage both the side shaft or the line-shaft sections and one or more pairs of gears.

This is a patented clutch action, employed by the Modern Tool Company in their line of chucks, which permits the chuck to be slipt into a tool-spindle collet running at high speed, and firmly engaged therewith, or to be disengaged and removed, without stopping the tool live spindle in which the collet is fixt. This clutch action is herewith shown and gives a clear idea of the manner in which the engagement and disengagement are effected. The two balls are in slots in the walls of the hollow collet fixt by its taper shank in the tapered spindle seat, and the collet body is surrounded by a

ly held up by the workman's hand, i leased and drops down by gravity, fo the balls to enter the chuck-shank gro while yet retained by the collet slot that the tool chuck-shank is held either sliding or turning in the c cavity until the collet sleeve is again l by hand, when the tool chuck will down by its own weight.

Fig. 11. Payne-Modern air-cooling fin con-

sleeve to the right hand line shaft member by motion to the right, or releases the gear sleeve and clutches the right and left line-shaft sections together by movement of the clutch sleeve, 5, to the left.

The side-shaft is tubular so that the balls can be moved by an interior sliding member, 6, having a cylindrical body with portions of its surface cut away so that this mutilated cylinder may be moved to right or left without clutching any gears to the side-shaft, but when stopt at a proper position will engage one and only one of the gears carried on the side-shaft with the side-shaft, thus obtaining one of the three forward geared speeds or the reverse. The side-shaft carries 5-gears, the large one at the left being keyed to the side-shaft, while the four-gears at the right, which are in mesh with the four-gears fixt to the line-shaft sleeve, respectively, are free on the side-shaft, save as they may be separately and individually engaged with the side-shaft by the proper placing of the internally sliding member, 6, which selects the desired geared speed change.

The side-shaft internally-sliding gear-selecting member is moved by means not shown in the plan of the change-gear. The three-ball clutch engaging elements, the rockers 4 and 5, and the unshown slide which effects the side-shaft engagements, are all so interlinked that all speed change operations must be made in proper sequence and the whole change-gear control is interlinked with the clutch so that no gear change can be attempted while the clutch is engaged with the motor shaft.

THE CHANGE-GEAR LEVER.

The change-gear lever swings horizontally, is fixt to a sleeve which turns inside the steering column, and has the handle and retaining lug jointed to the lever body so that the lug can be lifted out of the retaining segment notches when a gear shift is to be made, and can be dropt into the selected notch. This arrangement avoids the costly outside vertical gear shift lever, and the need for reaching outside of the car body to grasp the lever, and is a decided improvement, tho the motoring public has become so wedded to certain control forms, among which two or three outside hand levers copied from foreign practice are included, that it is hard to convince a prospective buyer that he is not being defrauded by the person who offers a simpler and better arrangement.

Fig. 12. Diagram showing the Payne-Modern motor car change-gear selection. The "Modern" change gear keeps all gears in constant mesh and makes the speed selections by clutching the requisite change gear assembly members together by the radial movement of steel balls, as determined by the moving of the change gear hand-lever. For complete details see text.

STEERING AND CONTROL.

The steering shaft has a quadruple threaded screw at its lower end, engaging a trunion nut in slots in the forked top member of the steering bell-crank. The hand wheel makes 1½ turns for the full sweep of the front wheels. The usual spark and throttle levers are on top of the hand wheel. There are no outside hand levers to block the car entrance. The foot board has three large pedals and a plunger pedal for opening the muffler, as shown in the rear view of the dash. Beginning at the left, this pedal, which is latched, when pushed forward first disengages the clutch and then applies the external brake bands to the rear wheel brake drums thru an evener, as shown

Hosted by Google

clearly in the picture. The middle pedal, pushed forward, first disengages the clutch and next unlocks the gear-shift so that gear-changes can be made. The right hand pedal when pushed forward first disengages the clutch and then applies the emergency, internal, rear-hub drum brake shoes thru an interposed evener.

The dash is of wood, with an aluminum "cowl," and houses the "Pittsfield" coil-box, and the 8 lead mechanical oiler, piped to each cylinder and to the crank-box pits.

Fig 13.—Payne—Modern Car. Diagram illustrating the ball clutch arrangement used in the change speed gear. This is the device which has been successfully used for retaining the shanks of drills in chucks. The left hand figure shows a drill shank disengaged. At "S" are recesses for the steel balls, and when the shank is pushed upward into the collet (as shown in the right hand, engaged, view) and the movable sleeve dropt downward as shown, the balls are forced into the notches "S" thus locking or clutching the drill shank and causing it to move with the collet.

The cranks shaft journals and wrists and pistons are splash-oiled. The gear box has oil pools in the bottom member. The fan is cone-clutched to the triangular-leather-belt-driven-fan-sleeve, the clutch being under fan-governor control to avoid waste of power by a too rapid fan motion. The fan-cone is of fibre. The fan is considered needful for cooling this motor.

ON THE ROAD.

The only Payne-Modern 6-cylinder car available was new and had never even so much as made one turn of its crank-shaft. This new Payne-Modern six, with two passengers in the Tonneau, Gilbert Loomis, the designer, driver and the writer as observer, in the front-seat, left the Modern Shops in Erie at about 3.20 p. m., and was driven over the shore road to Dunkirk, N. Y., 50 miles and return. This round trip is about 101 miles over gravel roads, mostly of bumpy and uneven surface, tho some of it is very fair for short distances.

The route is thru little villages which have low-speed rules and are very prompt with fines for cars which fail to slow down. With these speed regulations no time could be made, and this 100 mile run was merely a spring-action demonstration. The front, right-hand cylinder constantly over-oiled itself from the crank-box; why, no one could tell. The same thing had been seen before with one of these Payne-Modern six-cylinder motors in which the left-hand rear cylinder behaved in the same manner. This over-oiling made the motor run on 5-cylinders a good part of the time, as the spark-plug of this one cylinder. fouled every 5-miles or so. When this spark-plug was clean, the car was very lively and could show 45-miles wherever the sign-boards permitted pace. We made 50-miles or more to Dunkirk, in about 140 minutes. We cleaned that one spark-plug every few miles in the run back from Dunkirk, reaching Erie at 9.20 p. m. Circumstances prevented another long run on this six-cylinder which had been planned with a view to measured fuel demonstration.

As to the springs, the writer had several short runs on the Payne-Modern half-elliptics before making this 100-mile trip, and had learned in the first half-mile that the 15 deg. angle of the half-elliptic spring placing, wholly changed the effect of road surface variations on the car body and passengers, making it very different from anything in previous experience. Not only can this car, be driven rapidly over a rough road without undue shaking of the passengers, but there is absolutely no tossing of the car body at any time, so that over a close succession of bumps and hollows, where a car body on horizontally placed half-elliptics would be bounced up and down with unendurable violence, tossing its passengers up off their seats and catching them with another bounce as they came down, in a manner all too well known to American motorists, the Payne-Modern merely indicated the road roughness by a rather lively movement of the car body, but did not toss things at all. In fact, in this Erie-Dunkirk 100 mile round trip over rather rough roads, made at from 25 to 45 miles an hour, in many places, the observer was not once tossed up clear from his seat, and after the first reassuring ten miles he ceased to "ride the road" at all, simply sitting back and trusting all to the inclined car-springs.

It does not seem possible that the mere tipping up of the front spring ends could possibly cause such surprising advantages, but this most agreeable change in the spring action is indisputable, and makes the cars extremely easy riding.

The new motor was very stiff in this run, but the exhaust was perfect, no "cadence" when the front right cylinder spark-plug was clean, showing that all six cylinders were equally charged by the "turtle" and the performance of the Payne-Modern six was perfect in every way save for the one over-lubricated cylinder and its foul spark-plug.

The air-cooling was satisfactory, polished spots on the cylinder heads showing pale straw-color on the front and rear cylinders, and dark straw-color on the middle cylinders, with no sign of over-heating at any time.

Studebaker

Announcement

To our Model "H" Studebaker 30, the marketing of which we shall indefinitely continue, we have added a variation thereof known as Model "A". The only essential difference between them is that Model "H" has semi-elliptic rear springs and Model "A" half-platform rear springs. These cars are essentially five passenger cars. Between the two models all preferences and service conditions, affecting this power and size of car, are met.

The public is already familiar with the mechanical details of these two models.

Besides these models we are offering for the first time our Model "B" Studebaker 40, the design of which is practically an adaptation of the principles of the "H" and "A" Models to the requirements of a larger car, the mechanical specifications of which are briefly as follows:

ENGINE: 4¾x5½. Make-and-break low tension ignition.

WHEEL BASE: 114 inches.

CLUTCH: Conical.

CHANGE GEAR: Selective type; 4 speeds ahead with direct drive on third.

BRAKES: Operative and emergency brakes both on rear wheels.

CAPACITY: Seven passengers.

In body design and equipment we have been giving especial attention to comfort of driver and occupants and in order to reconcile these comforts with the best possible style, we have not hesitated to retain the best available experts to advise with our own well qualified and experienced staff.

We have taken a number of early contracts and retail orders for both closed and open vehicles of all three types, but can accept orders for Model "H" open cars about October 1st; for Model "H" closed cars during the month of October; for Model "A" open cars during the month of November; for Model "A" closed cars during the month of December; for Model "B" cars, both closed and open, during the month of December.

All of these models have been developed on the conviction that arbitrary changes of design, made at fixed calendar intervals, tend to throw the burden of experiment upon the user. We have had no occasion at any time to make any radical changes in our design, but improvements are introduced whenever practicable and with due reference to the active selling season. Our object is to absolutely eliminate the experimental. We are not "showing off,"—we are trying to satisfy our buyers.

"Continental" Type K, 4-Cylinder Motor

The Continental Motor Manufacturing Co., of Muskegon, Mich., has added a new model 4-cylinder 4¼ inch bore by 4½ inch stroke, vertical self-oiling motor to its line. This new motor which is known as Type "K" retains all of the features of all previous models of Continental Motors, and is similar in general design to their types "H" and "HB" 4-cylinder, 40 and 45 H. P. vertical self-oiling motors. It is of a nominal 24 H. P., and is brought out in response to the demand for a light high grade motor, suitable for light weight touring cars and runabouts. The main features of this new motor are extreme simplicity in design and construction, due to the small number of parts. There are only three spur gears incorporated in the design, and these take care of the cam operating mechanism, water, pump, and also the magneto if used. The magneto and water pump are located at the side of the motor where they are very accessible.

Side and end sectional views of the "Continental" Type K, 4-cylinder motor.

The valve operating mechanism is extremely simple, the plungers being of the mushroom type, and the valve plungers as well as the cams which are integral with the cam shaft are all carefully hardened and ground to size. The valve timing is also accurately marked on the flywheel.

The crank shaft has extremely long bearings for this size of motor, and they as well as the connecting rods are provided with sheet metal liners so as to be easily taken up for wear.

Cylinders, pistons, rings, crank shaft, cam shaft, gudgeon pins, valve stems, and valve stem plungers, as well as every small part of the motor are accurately ground to size and positively guaranteed to be interchangeable.

The connecting rod is of drop forged steel, and the bushings of white bronze as are also the crank shaft bearings.

Attention is also called to the automatic oiling system contained in this motor. This is a development of the oiling system used on their larger motors, and is adapted especially for small motors. With the special construction of the oil pan adopted it is impossible to cause flooding or smoking on severe gradients or hills.

The water circulating pump used is of the centrifugal type. It is located on the side of the motor, and is of the double bearing style. The pump is provided with a drain cock, and fitted with an extension to drive magneto, and a bracket is also furnished with these motors on which any standard make of magneto may be mounted. The exhaust pipe can be furnished as shown in cut, bringing it on the left side of the motor, or can be brought down on the right side either at the front or rear.

Every part of these motors are built by the Continental people in their own shop, which is especially equipt with high grade machine tools and appliances for accurate workmanship.

The company has just completed a new testing house which enables them to operate and test forty finished motors at one time. These large testing facilities enable them to thoroly test each motor under full load for a sufficient period of time to detect any weaknesses that may develop. After testing, each motor is taken down and carefully examined, and all bearings are taken up, if necessary, and motor carefully cleaned up and all grit, etc., removed.

The Continental Company is now well established in its new factory at Muskegon to which an extensive addition has recently been made, and as motors only are being manufactured large quantities can be turned out.

TION OF THE COMING SEASON WILL BE THE STARTLING 40-45 H. P.

Cleveland

1908 Model AT $3,500

This king of cars—the car that never has failed to *make good*—has more selling features of unapproache quality than any other car in America *absolutely without exception.*

Just read through these specifications. They do *more* than "speak for themselves"—they *shout* al to the dealer who wants a car that sells itself and to the man who knows a *perfect* and "up-to-the-minu machine when he sees it:—

MOTOR: 4-cylinder, vertical water cooled. Cylinders cast in pairs, with integral water jackets. Bore 5 inch, Stroke 5 inch.

IGNITION: Jump Spark. Imported Bosch high tension magneto, also auxiliary and independent coil and storage battery. Spark plugs for magneto circut over inlet valves; spark plugs for coil circuit over exhaust valves. Coil used is single unit Connecticut with distributor.

LUBRICATION: Positive Feed mechanical oiler self-contained in motor. Oil reservoir carried as an integral part of lower half of motor crank case with capacity of three gallons. Overflow holes in oil pan of crank case keeps oil at constant level at all times.

CARBURETOR: 1908 Schebler. 1½ inch size. Water Jacketed mixing chamber.

VALVES: Mechanically operated; inlet and exhaust valves on right hand side of motor. Valves interchangeable.

COOLING SYSTEM: Mayo Radiator, New Cleveland type and shape. Large gear driven pump, also liberal sized drawn copper water tubes and connections. Radiator fan, and also fan cast in fly wheel.

GASOLINE TANK: Twenty gallons. Large dirt trap between tank and carburetor.

CONTROL: Spark and throttle levers of new and distinctive design on steering wheel, segment stationary and independent of steering wheel, and foot accelerator independent of hand-throttle lever. Steering wheel, mahogany, 18 inch in diameter, with aluminum spider.

TRANSMISSION GEAR: Selective type, four speeds forward, and one reverse with direct drive on third speed. F. & S. Annular Ball Bearings.

CLUTCH: Multiple disc, running in oil.

REAR AXLE: Shaft drive, clutch-driven hub, ball bearings.

BRAKES: Emergency and foot brakes, large internal expan in rear hub drum, and dust-protected. Double-acting brake sh holding either backward or forward in both the emergency foot brakes; both brakes bronze against steel. Emergency b lever pulls toward operator to set brakes. Emergency brake a matically releases clutch. Foot brake does not release clutch

RATCHET-SPRAG: On transmission shaft drum. The pa this ratchet-sprag has a unique construction with spring cus preventing shocks to transmission and rear axle when spra applied.

FRONT AXLE: Drop-forged I-beam section with large ball ing steering knuckles; reach rod between steering connectio located back of front axle. Front axle is placed flush front of radiator.

FRAME: Cold rolled pressed steel channel section. Drop f with arch over rear axle.

HOOD OR BONNET; Aluminum 16 ga. Radiator and dash flanges have raw hide lacings to prevent rattling of hood.

SPRINGS: Semi-Eliptic front, semi-eliptic rear with plat (three-point) rear suspension.

WHEELS: Touring Car wheel equipment. Front 36 x 4; Re x 4½; Roaster Wheel equipment, Front 36 x 3½: Rear 36 x 4

WHEEL BASE: Touring Car 122 inch Roadster 110 Tread 54½.

DASH: Mahogany bound with solid brass molding.

BODY: Metal panels. seven passenger, "straight line" type

N. B.—Heretofore the Cleveland Chassis has been the same as the chassis used in two other well known c The 1908 Cleveland Chassis is distinctly our own product.

rior View The Phelps Vehicle Recorder.

tized dial, revolving one turn in y-four hours, while the snail revolves nce in seven days, one-seventh turn e snail raising the recorder or her point up one-seventh of the space e edge of the dial. The inner line is nated as Sunday, the outer line or ne on the dial as Saturday, the timer being so controlled by a set spring it will remove the sensitizing from ilvered face of the paper as it is n under this scratcher. The dials are ated into hours, halves and quarters, istinctly marked A. M., P. M., noon ight. The printing of the numerals, is on silvered paper in special pro- ink that will not set to the paper, an be scratched off with the instru- point, leaving a white record on blue round. This scratcher or vibrator ling point is operated, while the re-

uniformly wide line, indicating the exac elapsed time of the vehicle's movement When the vehicle is stationary, the sens tized dial still traveling under the pointe which is steady, shows a perfectly straigh thread-like line.

The clock movement and recordin mechanism are housed in an aluminun case with brass screw lid, and fitted wit a lock. The lid has on its inner side dog that records on the dial every tim the lid is unscrewed. As this dog canno pass in its arc without engaging th scratcher point lever, which raises th point up half way at each turn of the lid a record of each unscrewing of the lid i made on the dial at the exact day an time the device is opened or tampere with.

A very important feature of the device is the fact that it is self-contained, and no connected mechanically with any moving part of the vehicle.

The 1908 "Peerless" Jack

The Oliver Manufacturing Co., 203 South Desplaines street, Chicago, Ill.. ha just placed on the market their 1908 Peer less jack, shown herewith.

The leverage in this jack is claimed to be 50 per cent. easier than in their old style No. 15. The handle, of iron, is 15 inches long and weighs less than a pound.

The 1908 Peerless Jack.

The handle serves as a very efficient tire tool, and can also be used as a hammer. To raise the car, the handle is worked below the level, and to lower the car, above the level. The handle is long enough to work under any car. The weight and price of the new jack are the same as for their No. 15.

Seven Thousand Five Hundred Miles

Another Proof of Hartford Tire Quality

This cut is made from an actual photograph of a section of a

Hartford Tire

28x3 run by Dr. P. J. Ryan of Hartford, Conn., 7,509 miles by Odometer.

Note carefully that this tire is in practically perfect condition.

It pays to buy the best in tires.

You'll remember the quality a long time after you have forgotten the price

Most manufacturers equip their cars with good tires; some are not s particular.

Protect yourself by specifying and insisting on

Hartford Dunlop or Clincher Tires

There's no secret about the widespread popularity of Hartford Tires. They'r absolutely right, made of the best material by men of long experience with determination to excel.

FREE - A book that shows by pictures how to put on a Clincher or Dunlop Tire. Every Owner, every Driver, every Dealer should have it.

MODEL A. Price $900.

MOTOR—4-cylinder, aircooled, developing 12 H. P. and over.
CYLINDERS—3¼ in. bore x 3¼ in. stroke.
IGNITION—Jump spark, Pittsfield coil.
TRANSMISSION—Sliding gear,—three speeds forward and reverse, direct drive on high speed.
CLUTCH—Contracting band type, operated by foot lever.
LUBRICATION—Force-feed type, with sight feed on dash
STEERING GEAR—Irreversible type. Throttle and spark levers on steering column near driver's hand.
AXLES—Front,—tubular,—with ball bearings in wheels Rear,—divide, live axle running on ball bearings.
BRAKES—Two, of the contracting band type, operated by foot levers.
BODY—Of wood, with divided front seats; seating capacity, two.
COLOR—Dark Green.

The finish throughout is of the best, only first-class materials being used. Send for complete description of this most reliable and economical car, good for every day in the year.

Universal Buggy Type Engine

The One Best Engine For Buggy-Type Automobiles

Suitable for any light runabout or light delivery wagons, but designed especially for buggy-type rigs.

Two cylinders, 4x4 double opposed.

Conservative power rating, 10-12 H. P.

Weight, including flywheel, 180 lbs.

Over all dimensions, including spark plugs: length, 30″; width, 16¾″; depth, 17″. Depth without flywheel, 11½″.

Perfectly balanced. Entirely free from vibration.

Air-cooled, and **cooled** beyond question. Has been run at full speed for six hours without a sign of distress. Big exhaust valves. Careful construction. Best materials.

Every engine fully guaranteed to deliver the rated power and keep cool.

Prompt delivery on any quantity to those who order promptly. Attractive prices in quantities.

"Burgess" Double Tension Spring

In the accompanying cut is seen a new form of spring construction recently placed on the market by Charles H. Burgess, Jr., of Wenona, Ill. The advantages claimed for this spring are that there is no rebound of the car body, having the same elastic force above the horizontal line as below it; that there is no sidewise distortion of the body, and that the forward and back thrust of the body and twisting of the springs are eliminated.

Referring to the accompanying cut the axle (15), to which the wheels thereof are secured, is attached to the springs (20) by means of the plates (14) and clips (13), which is the common form of construction, the spring (20) consisting of a center leaf as shown, with laminations secured thereto on each side. The number of laminations that are employed depending entirely upon the strength of the spring required. The laminations being interposed on each side of the main or central spring (20) guards which are formed integral therewith and on each side thereof, are provided, thru which vertical guides are slidably mounted, having eyes (12) at each end thereof in which the roller bearings (11) are journaled and are normally in contact with the upper and lower leaves. When the spring is deflected there is a movement of the laminations, either forward or backward, longitudinally of the main spring and by the employment of the vertical guides (10), the laminations or leaves are kept in alignment during this movement, and are greatly assisted by the roller bearings which eliminate the friction between the leaves to a great extent. The depending hangers (18) are not preferably constructed, as the cylinders may be secured either above, below, in center or on ends of same. In the cut they are shown secured above, between the depending lugs, with bolts (16), which pass thru the eyes at the lower portion of the depending hanger (18), as well as thru the aperture formed integral with the cylinder casting. This construction gives the cylinder a free, vertical, rocking movement between the lower portion of the depending hanger (18), thus eliminating all friction of working parts of construction, the longitudinal axial line of springs and buffer springs being in the same horizontal plane. The cylinder (17), and its head are cast in one with the head aperture to receive a packing gland (7), thru which the piston rod (6) is adapted to slide. Adjustably mounted upon the piston rod (6) is the piston (1). The adjustable feature is accomplished by means of the piston rod being threaded as shown and adapted to cooperate with a bore provided with a female thread within the piston. The piston is provided with a cross sectional slot for the purpose of receiving the key which passes thru and within the apertures in the piston rod (2). Interposed between the piston and cylinder head of the cylinder is the buffer spring (5), the size of the buffer springs being governed entirely by the end tension sought to be given to the main spring (20). Each cylinder is provided with an oil plug (9) in order that oil may be inserted within said cylinder, the oil not only serving as a lubricant, but also acting as a fluid brake, inasmuch as each cylinder is completely filled with oil, and upon the forward or backward movement of the piston the oil is forced on either side thereof thru the longitudinal aperture (4), thus giving resistance to the piston according to the movement thereof, allowing the spring to move quickly when idle or worked on and slow when working, that is to say, absorbs the jars in the movement

"Burgess" Double Tension Spring; 1, Piston; 2, Key aperture in piston rod; 3, Cylinder cap; 4, Longitudinal aperture in piston; 5, Compression spring; 6, Piston rod; 7, Packing gland; 8, Spring bolt; 9, Oil plugs; 10, Vertical guides; 11, Roller bearings; 12, Eyes at each end of the vertical guides; 13, Clip; 14, Spring plate; 15, Axle; 16, Hanger bolt; 17, Cylinders; 18, Hangers; 19, Frame; 20, Main spring; 21, Slot in piston rod for main spring.

the heat and not be lost in cooling the hood or other parts. Upon the effectiveness of the air-cooling system the results obtained with these motors are based. The claim is made that with the same amount of lubricating oil as used on a water-cooled motor the same work is done without premature firing.

FLEXIBILITY.

As it is often claimed that the two-cycle motor is not flexible, the company states that its demonstrating car with 34-inch wheels and geared 3 to 1 can be driven on the high gear from 5 to 50 miles an hour which is as good as obtained with 4-cycle motors. The motors are also light for their power, as will be seen from the following: Four-cylinder, 300 pounds, 40 H. P., $350; 3-cylinder, 250 pounds, 30 H. P., $275; 2-cylinder, 200 pounds, 20 H. P., $200; and the small 2-cylinder, 130 pounds, 10 H. P., $135. The equipment includes spark plugs, carburetor, piping, ball bearing fan and air casing. A small marine motor of the same general design and workmanship, but of 3 H. P., is marketed for $45. All motors are guaranteed.

The Iversen Rear-Axle Transmission

A novel construction of bevel gear drive rear-axle in combination with the transmission and equalizing gears, is offered the trade for the coming season by The Iversen Mfg. Co., Pittsburg, Pa.

The transmission is of the planetary type, differing from the ordinary gears of this type, in that it gives three speeds ahead and one reverse; and also that almost any practical speed ratios can be obtained. The standard model 2 for up to 60 H. P. has a bevel gear reduction of 3.2 to 1, which is equal to about 40 miles an hour with 36-

Fig 1. Rear view of the Iverson complete floating type axle, with hubs carried on annular ball bearings, internal and external hub brakes and gear casing in the center.

inch driving wheels, when engine is running at 1200 R.P.M. The second speed is 23; the third speed 11 and the reverse 8½ miles an hour. The bevel gear reduction can be changed at customer's option. This will change the other speeds in proportion.

By referring to Figure 3, it will be seen that the main bevel gear is mounted free to rotate on the axle on a very long bearing. The bevel gear rim which also has an internal gear, is bolted to the main spider. The latter has also a pinion at the hub which is not in the same plane with the internal gear. The spider is also provided with four clutch shoes and operating means as shown. The equalizing gear is of the ordinary spur gear type. A circular drum-like extension is cast integral with the equalizing gear casing, and extends thru the planes of the pinion and internal gear above described.

An exterior flange is provided at the outer end of this drum, to which the journals for three pinions are securely fastened. These pinions mesh with the internal gear of the bevel-gear, and also with a gear which is carried, free to rotate, on the extension drum. This gear has an extension suitably arranged for receiving a brake, which if applied gives the second speed forward. It will further be seen from the cut that the pin which carries the pinion in the equalizing gear extends thru the casing and carries journaled on it a pinion which meshes with the pinion of the main spider and also extends thru a suitable opening in the extension of the equalizing gear casing, and meshes with the internal gear. This internal gear is fastened to a brake drum, to which the second brake is applied when the third or low speed ahead is wanted. Of course, three pinions are provided, one each, on three of the six pins in the equalizing gear.

The above-mentioned brake drum incloses the equalizing gear casing, extending with a flange down over the end of same. This flange has an exterior gear wheel as shown in the cut. To the hub of the equalizing gear casing is also fastened, by means of a screw thread, a flange which carries three pinions. These pinions mesh with the gear on the prior mentioned brake drum

Fig. 2. Construction of the Iverson hub brakes. This axle makes the drive complete, and nothing need be placed under the machine except the driving shaft from the motor, the torsion rod and connections for the operating levers.

and also with an internal gear. If the third brake is applied to the exterior of this internal gear, a reverse motion is obtained. To obtain the high speed all brakes are released and held by means of springs so that they do not touch their respective brake drums. The clutch shoes in the main spider are then engaged; they grip the interior surface of the extension of the equalizing gear casing, thus locking same to the spider. The whole system of gearing then revolves with the main bevel gear, and all

Folding Tonneau for Ford Runabout

The Dayton Folding Tonneau Company, 1143 North Main street, Dayton, O has added to its folding tonneau line size suitable for the Ford runabout. This new size is the smallest tonneau the make, but is large enough for two grown persons and a child. It adds only about 40 pounds to the weight of the car, but is strongly made. It is meeting with great favor among Ford dealers, as many of their customers while wanting a car of that price desire one to carry more than two persons. The Dayton Ford tonneau is designed to harmonize completely with the car, and can be fitted in a few hours No touching up or painting is required.

The "Moss" Sand Tractor

Augustus S. Moss Company, Sandusky O., has placed on the market a sanding device for automobiles. This device is called the Moss Sand Tractor, and is said to be very useful on wet asphalt or other slippery surfaces. It consists of a box of sand in some convenient part of the car, a comprest air system and suitable piping and valves. A gage on the dash shows what air pressure there is in the air tank. The valve is pedal operated When the pedal is deprest air is released and carries the sand thru pipes to the rear wheels where the sand is scattered on the ground.

Stevens-Duryea cars will now be handled in Philadelphia thru a branch which has been established, and is in charge of Mr. F. Windsor.

The Ajax Grieb Rubber Company's plans for new additions call for three buildings of brick with a total floor space of 75,000 square feet on the west side of Olden street in Trenton, where about six acres of ground are owned by the company. New officers for the year were elected as follows: President, Horace De Lisser; vice-president Wm. G. Grieb; secretary and treasurer, Harry Grieb.

With the recent reorganization of the Dragon Automobile Company, John Kane Mills returns to active work from which he resigned last spring on account of ill-health. While there has been no radical change in the interests involved in the company's work, there has been a re-adjustment, which, it is believed, will in-

The 1908 "Newcomb" Diaphragm Carburetor

The Newcomb Carburetor Co., 1900 Broadway, corner Sixty-third street, New York City, have recently placed on the market the Newcomb Diaphragm Carburetor, which is claimed to be absolutely automatic, in that it consists of an extremely sensitive, ingenuously-constructed atmospheric regulating valve, which supplies the gasoline exactly as needed, and follows instantly every movement of the throttle.

The operation of the carburetor is as follows: When the engine is cranked and started a partial vacuum is produced in the carburetor proper. This vacuum is communicated thru the gasoline jet to the space below the diaphragm (E), which is normally filled with gasoline. The

The "Newcomb" Carburetor; Perspective view; J, Throttle lever; K, Tickler cam; L, Tickler pin; M, Tickler screw; O, Air inlet valve; S, Outlet flange.

space above the diaphragm is always at atmospheric pressure due to the air vent (T). The difference in pressure on the two sides of said diaphragm causes it to move downward, opening the gasoline valve (C). This action continues until the flow past the gasoline valve equals the flow thru the nozzle. The pressures on the two sides of the diaphragm are then equal, and it remains in a fixt position until the demand for gasoline is changed. If the demand is reduced the gasoline pressure raises the diaphragm, allowing the spring (N) to close the valve slightly, reducing the supply. When there is an increase in demand for gasoline, the pressure is reduced on the lower side of the diaphragm. The atmospheric pressure on the upper side of the diaphragm instantly forces it down, opening the gasoline valve to such a position that the flow of gasoline thru the jet equals the flow thru the nozzle, and a balance is again established.

The "Newcomb" Carburetor; Sectional view; A, Universal union nut; B, Universal union; C, Gasoline valve; D, Gasoline nozzle in jet; E, Diaphragm; G, Tickler; H, Throttle valve; N, Gasoline valve spring; O, Air inlet valve; P, Air inlet valve spring; Q, Nuts for adjusting P; R, Outlet to engine; T, Air vent.

The only adjustment necessary is that of the tension of the inlet air valve spring (P). The tension of this spring is changed by means of the nut (Q). This air valve (O) tends to hold up the vacuum when the air flow thru the carburetor is slow and unsteady as it is under conditions of light load or low speed, and makes a mixture of sufficient richness for these conditions.

When the engine is running at a fair speed or moderate load this air valve sets back out of action, and a constant mixture is maintained. This constant mixture is due to the shape and position of the modified Venturi tube which allows the air to flow in such a way that the gasoline flow is not affected by it. Therefore both the gasoline flow and air flow follow the same law, and the mixture must be correct if the gasoline and air openings have the correct relations.

W. A. Woods, formerly with the Oldsmobile Company, of New York, is now connected with the Cleveland Motor Car Company, as sales manager.

Harold J. Elsworth, previously connected with the sales department of the Maxwell-Briscoe Company, has taken the position of sales manager for the Colt Runabout Company, and C. B. Craske will be purchasing agent for the Colt company.

ANNOUNCEMENT
TO SPARK PLUG USERS

A Money-Back Guarantee
WITH EVERY
DIAMOND SPARK PLUG

The ONLY Plug which you can LOOK THROUGH and SEE THE SPARK in the cylinder

¶ Believing that proof is better than argument and that practical demonstration is the ***best*** proof, we make the following unexampled offer to Spark Plug users:

Send us $1.50 (Marine Engines $1.75) for each Spark Plug desired, in check, money order, stamps or cash, together with name of your car or engine, and we will send you, PREPAID, Diamond Spark Plugs to the amount of your order and under the following absolute

GUARANTEE

If within six months of date of purchase you are not entirely satisfied with the Diamond Spark Plug in every particular, write us to that effect, and the purchase price will be returned without question or quibble.

¶ Diamond Spark Plugs are made from the highest grade material throughout. The porcelain used is unbreakable, all metal parts nickeled and polished and cannot rust.

¶ There is no short circuiting. No packing to blow out. No cement or shellac used. The sparking points are non-corrosive throughout.

¶ These and other features make the Diamond Spark Plug a ***serviceable certainty.***

¶ Send to-day, while the offer is fresh in your mind, for your first perfect Spark Plug and end your sparking troubles.

is device is intended to eliminate the
ence in adjustment and difference in
element of the various vibrators on
spark coil. It is a well known fact
t is an impossibility to so adjust sev-
vibrators that they will act in exact-
e same interval of time after the
closes the circuit, and unless they

operating largely against each other. Th
K-W Master Vibrator entirely obviate

Wiring Diagram of the "K-W" Master Synchronizer.

this lack of synchronism and consequen
lack of power, by substituting for all vi
brators one single vibrator. It does no
matter within reasonable limits what th
adjustment of this vibrator is, for it vi
brates for every cylinder, and no matte
what its time lag is, it has to be the sam
for every cylinder, thus giving exact syn
chronism and placing the sparks in every
cylinder at exactly the same position o
piston and the same angle of crank shaft
just as would a high tension distributo
and a single coil. It is claimed to posses
a great advantage, however, over the high
tension distributor system, for it does the
synchronizing on the low tension side o
the circuit.

The "Reliance" Spark Plug

The Jeffery-Dewitt Company, of Newark, N. J., is placing on the market the Reliance Spark Plug, which, while resembling in appearance many other plugs, is said to refute many commonly accepted theories. Apparently impossible demonstrations supporting the claims of the manufacturers that their plug is short-circuit proof have been made with it, they say, like the test in water here illustrated.

The "Reliance" Spark Plug Sparking in Water.

The distinctive feature of the plug is the insulated sparking point which is a hair-like platinum wire entirely protected from corrosive action in the cylinder by being baked in and brought flush with the end surface of the porcelain. The spark in leaving this minute point is concentrated and intensified to such a degree that it is said to instantly remove by the intense heat and scouring action produced by striking the surface of the insulator any matter depositing on or near the point. Absence of short-circuiting matter makes it possible to utilize the entire energy of the battery and coil to produce maximum heat in a spark, thereby insuring regular and perfect ignition. The plugs retail for $2.50 each, and are put up in metal receptacles. For the trade these are packed in neat display boxes containing a dozen each.

Mr. G. G. Westerfield, secretary of the Westerfield Motor Company, Anderson, Ind., manufacturer of gasoline engines, has been engaged by the Staver Carriage Company of Chicago, as superintendent of their automobile department.

As a convenience to their numerous clients who now tour Europe in Pierce machines, the George N. Pierce Company

These motors are also furnished with tra mission gears,—the motors being moun on sub-frame.

OUR CYLINDER AIR-COOLED MOTOR
Mounted on sub-frame, with sliding gear ansmission, three speeds forward and re-rse. The cylinders are 4 x 4, and it de-lopes from 18 to 20 H. P. We also furnish her sizes mounted or unmounted as desired. With a double chain drive, this motor is pecially recommended for commercial cars d trucks.

Two-Cylinder Horizontal Motors

with transmission gear, for either chain or shaft drive.

For All Standard Makes of Cars

poppet valves has been placed on
market by the Detroit Steam Engine
15 Gilman street, Detroit, Mich., and
nade in three forms. Model "C" is a
linder, 3&6x3½-inch, 20 H. P. motor;
el F a 6-cylinder, 3&6x3½-inch motor
0 H. P., and Model L a 6-cylinder 4&8
-inch 60 H. P. motor. List prices are
pectively $400, $600 and $800.

hese engines can be instantly changed
n compound to simple, a slight move-
t of the lever admitting high pressure
m to all cylinders. The same lever
rols the cut-off and reverses the en-
, which can also be used as a brake
closing the poppet valves, and thus
g the compression on the pistons.
s, it is said, is not detrimental to the
ne.

he cams are so constructed that the
m may be cut off at any point of the
ke down to three-fourths, making the
ne very economical. The engine can
installed with either end forward, as
steam can be admitted and exhausted
ither end.

cLachlin Model C, 4-cylinder, poppet valve steam engine,
3 and 6 inches; stroke, 3½ inches; develops 20 H. P.
$400.

he engine has no receiving chamber,
s, or any other spaces between the
nders to absorb the heat from the
m, which is working from the moment
nters the inlet valve of the high pres-
cylinder until it is entirely absorbed
the low pressure cylinder, if so de-
d.

he cylinders of the MacLachlin engine
cast in pairs with valve seats and
m ports integral. They are lagged
asbestos and cased with Russia iron.
lagging on the heads is covered with
vy, polished aluminum.

he aluminum crank case is in two
s with the center bearing bracket cast
he upper half, allowing the removal
he lower part without disturbing the
ings, etc. Large, removable plates
also provided on the sides.

The connecting rods are of cast ste
this model being used to prevent heat b
ing carried from the pistons to the cran
pins. They are fastened to the piston
by yokes which are screwed thru the pi
ton head and locked with a nut. Th
crank shafts are hammer forged fro
steel, and made to fit either way in th
engine. The main bearings are 3½ inche
by 1⅝ inches, and run in nickel babbi
bushings. The crank shaft and connec
ing rod bearings are of nickel babbit
made in a shell mould and interchang
able. The cams are of hardened stee
and the valve lifts have each a ¾-inc
hardened steel ball held in a socket whic
rolls over the cam and minimizes wea
When the cams are in neutral position th
valves are closed. By sliding the cam i
either direction the engine is compounde
and the steam may be cut off at any d
sired point, and a further movement
the cam in either direction will simpl
the engine, and thus practically double i
power.

This engine is designed to run withou
lubricant in the steam, as the splash i
the crank case is sufficient. On the dow
stroke the compression in the crank cas
is released thru a large check valve, bu
on the return stroke the air must com
thru any leakage space there may b
about the bearings. As the leakage woul
not be sufficient to supply the crank cas
with atmospheric pressure, there is
slight vacuum and the lubricating oil wi
not escape thru the bearings.

The Newcomb Carburetor Co., 190

Carburetor Troubles

with the

Rutenber Carburetor

It overcomes completely all the troubles common to most all carburetors. It makes a poor engine good and a good engine better and increases the power 25 per cent. It is unaffected by atmospheric conditions and is reliable always. You can be sure of reliable carburetion under all speeds.

We can prove every claim we make and urgently request every manufacturer, individual owner and dealer to write for information, which will be cheerfully furnished.

Write to-day.

BOSCH IGNITION.

is without question the most perfect ignition system produced in the World. The leading automobile manufacturers of America, France, Italy, Germany, Switzerland and Belgium equip their cars with Bosch Magnetos. Their unqualified indorsement and continued use of the Bosch Magnetos is a guarantee of their worth.

In all of the world's great automobile races the Bosch Magneto has proved its superiority. The result of the Grand Prix Race Shows that out of 38 cars entered 28 were equipped with Bosch Magnetos including the winner (Fiat) the second car (Renault) the third (Brasier) This fact demonstrates beyond a doubt that the best ignition system is the Bosch Ignition System. Be sure your 1908 car is equipped with a Bosch Magneto.

Warning Against Imitation

Possibly the highest compliment that could be paid to the Bosch Magneto is its imitation by unscrupulous manufacturers who are endeavoring to copy the Bosch Type "D 4" Magneto. This has been so cleverly done that anyone unfamiliar with the machine would fail to note the difference.

See that the word "BOSCH" is stamped on the Magneto when purchasing.

The Complete Victory of

Goodrich Tires

The Successful Choice of Glidden Tourists

From the stand point of results the sweeping victory of Goodrich Tires in the 1907 Glidden contest is the most complete and convincing set of tire evidence now offered to prove tire value.

The start showed Goodrich Tire popularity.

More cars equipped with Goodrich Tires than any other make and equalling the combined number of all other makes.

The finish showed Goodrich Tire worth—actual, tangible road evidence of mile in and mile out wearableness verified by the fact that every trophy winning car in both the Glidden and Hower contests were successfully carried from start to finish on Goodrich Tires, also **not a single car in the contest equipped with Goodrich Tires was penalized for tire troubles.**

lown in section, the illustration being uitably lettered to make clear the de-cription which follows:

The gasoline enters at "A," and is then ltered thru a gauze "C," after which it oes thru the needle valve "D."

The throttle plate "J" contains four penings (not shown) in its surface, corre-ponding in shape to the equilateral trian-es, which, upon the throttle lever "K" eing moved, causes these triangular penings to move across other rectangular haped openings in the face of the mem-er "Y," thereby forming triangular shap-d openings for air inlets in the bottom of e carburetor with the moving of the rottle.

Sectional View "Scientific" Carburetor. Lettering fully explained in text.

The needle valve "D" is connected to e plate "J" by the pinion fastened to its ter end meshing into the rack con-ined by this plate. As the valve "D" is readed into the member "Y," moving e plate "J" causes the needle point of)" to unseat in direct proportion to the ening of the throttle; consequently the nount of gasoline allowed to enter is al-ays directly proportional to the amount air admitted. Since the cut shown was ade a method has been adopted where-the length of the arc thru which the edle valve revolves can be accurately justed to engines differing as to bore d stroke.

At the opening of the inlet valve of the

against the hot plate of the member leaving the carburetor thru the pipe nected at "O," a perfectly proportio and thoroly homogenous gas, and no mist, it is claimed by the makers.

The exhaust pipe from the engine connected at "P," and upon the open of the exhaust valve the rapidly mov exhaust gases cause the ball bearing bine wheel "R" to revolve at a high ve ity, and this wheel, retaining its mom tum, after the first exhaust pressure sides, continues to draw the burned ga from the cylinder, thus securing a m complete scavenging of the engine.

The five main members of the carbu tor body are clamped together by crab "U," thus making possible an alm instant disassemblement, if for any ca it is ever found necessary, and furth makes possible the easy setting of members "P," "O" and "Q" in any di tion which may be most convenient the attachment of the pipes.

JEFFERY DEWITT COMPANY

vely to the manufacture of lenses and ass parts of automobile lamps and archlights. Back of this factory is not ly the extended experience and knowl-ge of the proprietors, but the experi-ce of earlier generations of the Matisse nily who for over 50 years have made ses in France, and were early recog-zed by the French Government as ex-rts in this line. Carlo and Albert Ma-se, who are respectively president and e-president of the Matisse Lens Manu-cturing Co., have for many years been entified with the lens and mirror indus-es in this country, and this experience ggested to them the use of mirror lens lectors for automobile lamps.

The glass used in Matisse mirrors is de under the personal supervision of the tisse brothers to insure sufficient ten-e strength and correct optical qualities. is prest in molds and annealed to make capable of withstanding great heat and nperature changes.

The first process consists in smoothing d shaping the rough glass as it comes est from the foundry. This is done by nd grinding with steel and abrasive terial, and is continued with various grees of the finest Turkish emery. The s is then ready for the pumice wheels varying quality, which effect a clean nsparent surface on both sides of the s.

The next process is the polishing, first felt wheels, then on patent machines, h the finest imported rouge. This is icate work, and must be handled by perts to maintain an absolutely smooth face on each side of the lens, espe-lly on the convex side, for the silver cess to follow.

The lens is then washed with distilled ter to efface all impurities, and is then dy for the silver or reflective finish. e quality of the silver is the most es-tial factor in the entire work, as it is this medium alone that reflection of a manent nature is due.

After the silver bath the lenses are nged into a copper solution which as-s in retaining the silver; they then s thru a final solution and are painted h a special preparation.

The lenses are then placed on a special ussing apparatus to determine the ex-focus, are then trade marked, labelled become identified as the finished pro-t.

The special feature for the coming sea-

tread, which differs in construction fr the 1907 tread, and is said to be gree superior to the latter.

It is made of three thicknesses chrome leather full across, thru wh closely-set rivets with hat-shaped he

Fig. 1. Woodworth 1908 Tire Tread.

are carried, turned and clinched. T flange or brim of each rivet head prese an increased area to the surface of leather, insuring it greater protection a longer life.

All of the tread that can be injured the steel covering, etc., as shown in F 1, to shield it from punctures, cuts a abrasions.

By this new form and manner of c struction the makers claim to have creased the mileage more than 50 cent., as they have proved by actual t outs.

Fig. 2. Woodworth 1908 Tire Tread.

To protect the sides of the tread fr being scuffed and worn when run in r or against curbstones or street car trac a special Woodworth Tread is made w broad oval-headed steel rivets set cl together to take the wear and shield t tire, as illustrated in Fig. 2.

The outside strip formerly used now tends the full width. The new buckle a strap are stronger, more durable and ne er in appearance than the old.

Won't Slip Tread Tires

1

They hold their own; they hold the road,
And at no curve need they be slowed;
Upon the earth they keep their grip—
And Bailey Tread Tires won't slip.

2

They're Tires that hold the Right O' Way,
They've come to go—and come to "stay,"
And while you go the merriest clip
The Bailey Tread Tires won't slip.

3

They're "knobby" Tires that stand all strain,
The "Rubber Studs" are safe and sane;
The stretch of ice you need not skip
For Bailey Tread Tires won't slip.

4

For Auto, Auto-Bi or Bike
They lead in speed on track and pike,
They neither ravel, rend nor rip,
And Bailey Tread Tires won't slip.

5

They "corner" all the turns with ease;
No "Heart in mouth" if you have these;
No sudden short-turn brings a tip
For Bailey Tread Tires won't slip.

6

They are not skidders that **skidoo;**
All roads are pleasure roads to you;
The "Won't Slip" Tread, says every lip,
Is rightly named "Won't Slip." (A. W. B.)

The **world wide** popularity of the Bailey "Won't Slip" Tread Tire has been made entirely on its merits. The "mouth to mouth" advertising by those who **ride** them and who have found in them a tire which proves its **reliability, durability** and **superiority** over **any** and all anti-skid tire tread constructions has made it impossible for **8** of the largest tire manufacturers in the United States to supply the demand for Automobiles, motor cycles and bicycle tires with Bailey Tread. There is no **metal** in the Bailey Tread to **heat** the tire, **pull** loose from the rubber or **tear** the **road bed.** The **rubber studs** of the Bailey Tread are the **true** principle that give **perfect traction** and prevent **skidding.** They are to the Automobile what the **rudder** is to the **ship.**

N. B.—The extra cost of the Bailey Tread Tires on the List more than smooth of same make, is 2½ and 3 in., $1.50 each; 3½ in., $2.00 each; 4 in., $2.50 4½ in., $3.00 each; 5 in., $3.75 each.

N. B.—Now ready: Bailey's "Won't Slip" Tread Bands for covering all makes and sizes of smooth, new or partly worn tires at nominal cost by Bailey Tire Manufacturers. Write us for descriptive booklet.

C. J. BAILEY & CO.

Dealers' Department

The Halsey Automobile Company of St. Louis

The Halsey Automobile Company, of 3908-18 Olive street, St. Louis, Mo., is acting as agent for the Packard, Stevens-Duryea, Buick and Franklin cars, under the management of O. L. Halsey, president; H. H. Walker, secretary, and J. D. Perry Lewis, treasurer.

In response to an inquiry regarding advertising this company realizes the use of advertising mediums for securing new business, placing the "Automobile Trade Journal" first, and then newspapers. The company's success is due largely to the good results the customers have obtained from their cars, and it exerts a great deal of energy toward this end. The company uses the card index system in following up prospective buyers until a sale is consummated. After a sale is made the customers are kept in touch with from time to time. The company does not make a specialty of trading in second-hand cars, except to sell same on a 10 per cent. basis.

It is the belief of this concern that the principal trouble with agents in selling cars is first, cutting prices; second, trading; third, poor attention to customers after they have sold them. In regard to the precepts required to be followed by salesmen this concern demands that the salesmen deal in an absolutely straightforward and honest way, making no statements that can not be backed up, and also that they look after their customers after they have sold them. The salesmen are employed on a salary and commission.

A fully equipt garage for care and maintenance of cars is provided. The repair room is also well equipt with lathes, drill presses, etc.

Some experience has been had with grafting chauffeurs, but when found out they are "nipt in the bud."

Trading of Second-Hand Cars

As a rule most buyers of second-hand cars are as careful in their selection as those placing orders for the latest models, and are generally patient, and will wait for the car they want. The disposition of all the machines that have had but a year's use and possibly less, particularly at this stage of the industry, when the depreciation in value is not great, has become a wonder to the general public. But upon investigation among the big dealers an interesting condition exists, in that not one of them has any hesitation in taking in trade a car of standard make from a purchaser of the make they handle. But where do they go? One dealer, for instance, whose place is located on Broadway, New York, has a waiting list of buyers for second-hand cars of just such and such finish and equipment, and the minute he gets one of them off it goes. He has instituted an entirely new plan of dealing with them. On the third floor of his establishment he has a special room for overhauling and repainting them, and not one can leave his place until it shows the same efficiency as it had practically when new.

Retail Notes

The Diamond Rubber Company, of Akron, O., has opened a branch at 1207-09 Main street, Los Angeles, Cal., in charge of F. O. Nelson.

R. M. Owen & Company, of New York, in order to secure more convenient and commodious sales quarters, has leased the property at 1759 Broadway, which was formerly occupied by Smith & Mabley.

The G & J Tire Company has opened a branch for the sale of its product in Buffalo, N. Y., at 912 Main street, under the management of Mr. Frank Berrodin, doing away with the agency at 9 West Huron street.

The Collection Department of the New York Automobile Trade Association, recently established, is proving very successful. The association now has a membership of sixty-one local dealers and garage owners, making it the largest association of its kind in existence.

Manager John L. Snow, of the New England Peerless Company, at Boston, Mass., has kept a polished show chassis in his salesrooms on Columbus avenue all thru the season, and customers have taken much pleasure in studying the mechanism there revealed. Now that the season for closed cars is approaching Manager Snow has placed in his salesrooms a limousine body in the rough. Alongside is a finished body of similar style to permit comparisons. The rough body shows many points which are concealed when the body is finished. One of the cushions have been ript open, showing the method of putting in springs and curled hair. This, with samples of broadcloth and leather coverings, makes a complete exhibit of the Peerless quality in upholstery.

Commercial Motor Car Department

Experience of Commercial Motor Car Users

Laundry Co. Finds Motor Car Delivery Pays

Troy Steam Laundry, Auburn, N. Y., uses a 10 H. P. Cadillac Model M in collecting and delivering laundry. The loads average 300 pounds and the car makes about ten trips per day, totaling about 25 miles per day. Fuel expense averages $5.50 per month, lubricating oil, 50 cents and repairs $3. This machine, while costing more than a horse outfit, does about twice the work, and while this concern formerly used but one horse and wagon (total cost with harness, $395), it covered only about 15 miles per day, and two teams would be required to do the work the $1100 Cadillac machine is doing.

They are of the opinion that the car should, for their purposes, be of about 15 H. P. and geared low, so that its maximum speed would be about 15 miles per hour. Easy springs, 32-inch wheels, and solid tires are also recommended by this concern.

They find that drivers are too anxious to drive fast and believe that with a 15-mile-an-hour car solid tires could be successfully used. They had solid tires fitted to the rear wheels and have found that they are perfectly satisfactory at speeds at which such a car should rightly be run.

They calculate depreciation at 25 per cent. per annum, which is 5 per cent. more than for horse-drawn outfits.

Simpler and More Durable Cars Needed

According to the report of the experience of the Chicago office of the Standard Oil Co., commercial cars should have more durable tires, fewer and simpler mechanical parts and greater strength in vital parts.

They use two machines, a 14 H. P. Packard truck of 2 tons capacity and a 45 H. P. Biddle-Murray truck of 3 tons capacity. These cars operate in a radius of 5 miles and make 4 trips per day; total mileage of 25-30. The Packard car cost $2750 and the Biddle-Murray $3500. Ten horses and five 2-ton trucks were formerly used in this work, but each covered only about half as much ground as each motor car now covers, making but 2 or 3 trips per day. The horse-drawn outfits cost about $610 each.

The operating expense includes $30 per month for gasoline per car, $4 for lubricating oil, $50 for repairs and $75 for the operator. This is almost as low as the expense for the maintenance of the horse teams, which included $14 per month for care and feed of each horse, $2 for shoeing, $4 for repairs to each wagon and $60 per month driver's wages.

Like others, they have found that a good, careful, intelligent driver is essential to the success of a motor car in business use.

Fire Chief Pleased with Stanley Runabout

Chas. S. Allen, chief of the Trenton, N. J., Fire Department, writes under date of August 16 that he is much pleased with the service rendered by a Stanley steam runabout which he placed in service April 25 last. He uses a Model E X, 10 H. P. car, which weighs 1000 pounds and carries as high as 3 men to the fires. The mileage covered, of course, varies greatly each day, but probably averages 5 miles. The car cost $850 and has required practically no repairs so far. Fuel expense averages $6 per month and oil $1.

The horse formerly used cost about $14 per month for care and feed and $6 per month for shoeing. The value of the outfit was $560, and, of course, the same priced man runs the car that formerly drove the horse. The time saved in arriving at a fire is a great advantage, enabling the department to act more promptly and resulting in the saving of both lives and property.

Motor Car in the Auto Supply Business

Riverside (Cal.) Auto Transfer Co. use a 45 H. P. 1906 Stearns touring car in delivering automobile supplies. It averages 3 trips per day and operates in a territory of 100 miles radius. The car cost $4500, and a $100 per month operator with a $60 per month helper are employed. Repairs cost $50 per month; gasoline $35, and lubricating oil $4. This service is, of course, not a fair test of motor cars in business use, as the use of a high-priced touring car made for luxury and speed cannot, of course, be compared to a commercial car on the score of economy.

Five auto delivery trucks are now in use for the delivery of books to the sub-stations of the Chicago Public Library.

e rear springs are platform, 2½ in. wide, in. centers; cross spring 2½ in. wide and in. centers. The front axle is of 2½ in. beam construction and does not require usual bend in the center, giving greater d clearance, as will be seen from the cut. e rear axle is dead and is 2¼ in. solid are. Timken roller bearings are used. e frame is constructed of 2x5 in. sound , armored by ¼x5 in. steel plates. The od sill is shock-absorbing and with the el plate makes the frame firm and strong h no tendency to sag.

BRAKES.

Two independent sets of brakes are used. ey are of the contracting band type. The gular light running brakes are of such size to prolong the life of the tires, which is important factor. They are situated on side shaft, and as their adjustment can- t be affected by the radius rod, they al- ys remain the same. The emergency brake is transmitted to the radius rod, th by relieving the springs of this strain. B sets of brakes have long equalizers.

The wheels are second-growth hicko spokes 2-in. thick on front and 2¼ thick on the rear wheels. The drivi sprockets on the rear wheels serve as inner hub flange and are fastened by ⅝-inch bolts in the center and twelve inch bolts around the outside; these b pass thru the spokes and have a spe head to prevent the spokes from splitting

The interchangeable sprockets are cut the use of ⅝x1¼-inch Diamond roller s chains. The radius rod is a steel casti and acts as a shock absorber. There two especially designed universal joints tween the engine and transmission. T are dust-proof and can be taken apart qui ly without the aid of tools. The muf readily quiets the exhaust pressure and constructed so it can readily be taken ap and cleaned.

Improved Form Of The "Hubbard" Patent Wheel Tire

The Hubbard Patent Wheel Tire, manu- ctured by Arthur H. Middleton, 2821 N. oad street, Philadelphia, Pa., and de- ribed in our December, 1906, issue, page 3, has recently been improved by the addi- n of steel tread plates, as here illustrated. The tread of the new tire is made of cast

Section of New "Hubbard" Patent Wheel Tire, Showing the New Steel Tread Plates.

el plates which are placed on top of the bber cushions, thereby preventing the rub- r from coming in contact with the ground. his construction, it is claimed, will not re- ce the resiliency of the rubber but will otect it from being cut with stones, rocks, c., nor will it destroy the non-skidding

The machine is to be used as a po patrol wagon. It is to be of steel body, H. P., and large enough to carry eight policemen and the chauffeur.

The vehicle is to carry a good si squad of policemen to any point wh there is more serious trouble than the n immediately available can handle. It be able to go much faster than the p have observers there at that time.

Railroad Automobiles at Isthmus of Panama

The purchasing agent of the Pana Canal Commission has advertised for t automobiles suitable for carrying ten p sons each and capable of a speed of miles an hour on the railroad across Isthmus of Panama. The engines must stout enough to climb a grade of 8 per c and to increase their speed to 25 per c above normal, or, in other words, to m fifty miles an hour. The car must b ordinary stove gasoline and have a ca city to go 125 miles at full speed and lo It is the purpose of the commission place these cars in the inspection dep ment for the use of the chief engineer his assistants, who now have to rely passing passenger, freight, dirt or spe trains in inspecting the work along canal.

The high speed forward is omitted in the 1908 Meiselbach Trucks, which have only one speed forward and one speed reverse. The piston area is increased by making the pistons 6 inches diameter with the same 4½ inches stroke. The friction pinion diameter of 8 inches is retained, and the large diameter of the opposed gray-iron members is reduced to 22 inches. The maximum speed of the 1908 Meiselbach Trucks will be 10 miles, varied to lower speeds to suit intended service by changes in the numbers of sprocket teeth.

Three sizes of these trucks will be supplied in 1908, one ton, two tons and three tons paying load. The trucks weigh 3800, 4500 and 5000 pounds, respectively, and sell for $2,000, $2,500 and $3,000. The trucks are all of the same general appearance. Special bodies are fitted, however, for special service.

Now that the small gas engine is fectly "flexible," there is but very l if anything, to be gained by keeping piston area as small as possible; in the constant practise is to increase p area.

The increased cylinder diameter in 1908 Meiselbach trucks is an improver and permits any speed up to maxi tho the reduction from the motor to drivers has a constant ratio.

RELIABILITY OF FRICTION DRIVIN

At first sight, friction driving s much more likely to suit pleasure than commercial wagons, which mus powerfully driven to carry heavy l But all persons familiar with the per ance of friction driven passenger car well aware that the friction turns wheels just as strongly as the sliding

Fig. 2. Side elevation of Meiselbach Truck Chassis, showing the motor and friction c speed, the frame construction and the radiator and piping.

The 1908 trucks are made in three sizes of the same general appearance. The wheel bases are 84, 96 and 108 inches, and gage 60 inches. On the one- and two-ton trucks solid tires 34 inches by from 3½ to 6 inch face are used. In the three-ton truck the tires are 36x6 inches. A horizontal, opposed 4-cycle water-cooled 6x4½-inch motor is used in all three models.

NOTABLE FEATURES.

The distinctive feature of this truck is the single speed friction drive, same reduction ratio forward and reverse, which is discussed and illustrated and described in detail under various following subheads. No differential is used with this

turns them in slow work on mud sandy roads, and in all demonstra with friction driven cars witnessed b writer the friction drive has shown able to handle all the power of the as advantageously as the toothe transmission, with the very great of permitting the full power of the at high speed to be thrown on the mission without noise, shock or dang breakage. The sliding gear de skill and caution in handling, a therefore much inferior to the fri drive, which can be handled without or discretion, and without danger in charge of low-priced drivers.

e three-ton truck, 38 inches long by 3 ches wide, with 12 leaves. The brake rums, 18 inches diameter by 2 inches ce, are integral with the opposed friction ive members, and the fiber faced brake ands are pedal applied thru the usual 3-ole levers. These very large diameter akes, on the cross-shaft, are extremely owerful, and hold the truck securely un-er all conditions.

NO BALANCE GEAR.

It will be at once noticed by the motor r expert that this 1908 Meiselbach fric-on drive has no special means for driv-g the outside wheel faster than the in-de wheel when rounding a curve, such is supplied by the balance gear in the dinary forms of motor car drives. This ems at first thought to be a serious ob-ction, but in practice the truck runs per-ct y well, driving on curves as strongly, all appearance, as on a straight-away urse.

This will be less surprising to those who member that all railway locomotives d cars turn both wheels at the same te on curves, save for the small surface eed variation had by the slight coning the car wheels. Many attempts have en made to vary the speeds of the in-le and outside car wheels in rounding rves, but so far as the writer is aware

fixt to one axle, but each wheel is dri by a separate friction action, so that slip occurs between the paper frict pinion and its coacting, beveled, gray-i friction-wheel, with both the pinion

Fig. 5. Front axle of Meiselbach Truck I-section, steel drop-forging, no welds, rack pinion steering.

Digitized by Google

slight on curves of large radius, and there is no perceptible loss of power due to this slip. There is, of course, some loss of power by slipping, as it is work done with no useful effect, but a run of some miles on a country road with plenty of turns showed nothing different from the action of an ordinary truck with a sliding-gear and balance-gear of the usual form.

ON THE ROAD.

Saturday, August 31, a one-ton Meiselbach truck, with the single-speed-forward-and-reverse-friction-drive, all as shown in illustrations herewith, was loaded at the North Milwaukee factory with 2060 pounds of car wheels, Mr. Meiselbach driving and the writer as observer. The car was under perfect control, the large brakes holding it with ease on any incline, and a photograph was taken with the loaded car standing on a stiff grade, which does not show its real steepness in the picture.

The truck was driven seven or eight miles over a rough gravel road crossed by a number of trolley tracks, and having plenty of turns and one very sharp rise to a ridge, much steeper than the one shown in the illustration, but enclosed by high fences on each side, so that no picture could be taken.

The control was perfection, leaving nothing to be desired in the way of convenience, and was very easy on the driver. There was no vibration of the drivers seat or foot-board, and the speed was under such ready control that the car could be handled over obstructions very much better than is possible with a horse-drawn truck.

The pace seemed slow, but was more than double that of wagons drawn by walking horses. Several heavy wagons, both loaded and unloaded, drawn by horses were passed.

The very large brakes on the cross-shaft held the car to any desired rate of speed at all times and under all conditions, so that the wheels could be eased down any drop in the road surface with no jolting, and, as before said, the truck could be stopt and started readily on any incline the friction engagement permitting a start at full motor speed with no shock or jar. In a word, the friction drive was ideal in action, and the lack of the high speed. which might enable an unloaded truck to save some time, is more than balanced by the certainty that the truck cannot be driven faster than is prudent.

Motor Ambulance Service

One of the newest ideas in automobile construction is the recent product of the Rapid Motor Vehicle Company, of Pontiac, Mich. This is an ambulance especially designed for the peculiar needs of hospitals, sanitariums, city dispensary departments and others, requiring, in their service, an ambulance capable of making exceptionally quick runs and under varied conditions.

This motor car ambulance can be geared to attain a maximum rate of from fifteen to thirty miles per hour. The body is full panelled with seven bevelled glass drop windows, covered with curtains of the finest silk pantasote, assuring perfect light and ventilation. Entrance is made by means of two steps in the rear of the body, and along each side is arranged a full-size emergency cot.

There are seats on the inside for three attendants; one in the center of the forward end of the car and one at the foot of each cot. The driver's seat, which is of tufted leather, extends the full width of the bed, four feet six inches, and will comfortably seat three persons. Under the seat are two spacious drawers used for supplies. A gong is used instead of the regulation auto horn. The tires are three-inch solid rubber, which obviate the possibility of punctures or other tire troubles during emergency runs; while the full platform springs insure easy riding even over rough and hilly roads.

Max Gabrowsky has given up the general management of the Rapid Motor Vehicle Co., of Pontiac, Mich., to engage in a new field of work, and is succeeded by Harry Hamilton.

Mr. E. T. Shepherd, superintendent of the Chicago Fire Insurance Patrol, Chicago, advises us that for the last two years he has tried to find a motor car that would be suitable for his business, but has failed. He is in the market for one that will carry weight and have speed.

As a result of the agitation which ensued when the Mayor vetoed the Philadelphia Motor 'Bus ordinance, a new ordinance providing for the operation of motor 'buses was introduced in Council. This new measure provides that machines may be operated on Broad street, between League Island and the city limits, and on the full length of Diamond street. It also permits the vehicles the use of streets within three squares of the Auto Transit Company's proposed terminals, and in case of blockades the use of the nearest parallel street.

The great possibilities attending the use of automobiles as conveyors of mail over rural delivery routes are clearly shown by a test recently made at South Bend, Ind. The route selected was twenty-five miles long, supplied 115 families, and is said to be the hardest mail route in St. Joseph County. With a horse and wagon it takes eight hours to cover this route, but in the test the mail carrier drove a Studebaker electric and cut the time to three hours.

For Cleaning Auto Bodies

It's good to see how quickly Mobo removes mud, grease and dirt from an automobile body. It doesn't matter how long the car has gone without cleaning, or how thick the dirt may be—off it comes, easily and quickly if you use

MOBO

Automobile Cleanser

Not only does it remove all the dirt, but does it without marring or scratching the varnished surface, and without dimming the lustre in any way. That's Mobo style.

Mobo is composed of pure vegetable oils, and contains nothing rough to mark the smoothest surface. It is the ideal automobile cleanser.

Prevents the varnish and paint from cracking and blistering. Keeps the car looking new. It's the best sold to-day. Try it once and you'll understand why.

Put up in 3 lb. and 6 lb. cans; also in tubs, half-barrels and barrels. Can be had at the following supply house:

CHAS. S. SMITH & CO.
JOBBERS IN AUTO & MARINE SUPPLIES
Broad and Wood Streets,
PHILADELPHIA.

and at all good automobile supply stores in all leading cities.

Send for our Mobo booklet —"*How to Clean Well Varnish and Paint on an Automobile*" It's free.

THE PEDERSEN Mechanical Lubricator

Has earned the name of being

"The Best Oiler on the Market"

Type X

PATENTED
Mechanical Lubricator

BECAUSE—

There are no Check Valves or Springs to get out of order.

It can not gum up. Works in cold or hot weather with same adjustment.

Has constant Sight Feed.

And many other valuable features.

Ask your dealer about it, or write

icago Motorcycle Endurance Run

ree perfect scores with Walter Dav- leading was the result of the sec- annual endurance run of the Chicago rcycle Club, September 14 and 15, Kokomo, Ind., and return. Of the y entries received twenty-six started 414-mile run. At the end of the first run to Kokomo nine cars showed even of which were on time. On the n a few others dropt out, leaving three clean scores, which were Wal- Davidson, riding a Harley-Davidson; ge W. Lyon, riding a Torpedo ma- e, and Fred Jergenos on an Indian. er Davidson made the best showing, ng thru without any tire trouble and adjustment whatever on his machine. made the best record in the shortest , making the distance between Koko- and Chicago in 8 hours 30 minutes. schedule time being 12½ hours.

"Hilaman" 3½ H. P. Motor Cycle

ne A. L. Hilaman Co., Moorestown, ington County, N. J., now manufac- s a 3½ H. P. model of the Hilaman or cycle. The cylinder is 3¼ inch by 3½ inch stroke, and is fitted with e valves 1⅝ inches in diameter. Two heels, 8¾ inch diameter and 1½ inch bronze. The crank shaft is of tool steel A hollow ⅝ inch wrist pin is used. The crank pin is ⅞ by 1⅝ inches in diameter and the main bearings 1x2 inches.

The piston is very light, and is 3½ in ches long and fitted with 3 rings ¼ inch wide, step cut. The connecting rod is o drop forged steel. The equipment con sists of Splitdorf coil; Corbin Duplex coaster hubs; Goodrich or G and J tires 2¼ or 2½x8 inches. Long bars with grip control are used. The wheel base is 5 inches. Weight complete is 170 pounds The price of machine complete is $210.

Motorcycle Races at Wheaton

The following is the result of the motor cycle race meet at Wheaton State Fair Grounds, September 13, under the auspices of tne Chicago Motorcycle Club:

Three-Mile Exhibition Race—George W Lyon riding 5 H. P. Simplex Peugeot time, 4.02.

Five-Mile Race—C. S. Hinkly, ridin Harley-Davidson, first; time, 6.55, wit George W. Lyon, Simplex Peugeot, second

Three-Mile Exhibition Race—A. J. M Cullon, riding Racycle; time, 4.45.

Second Meet of Philadelphia M. C. Clu

M. M. FOR 1908

AND ready for immediate delivery. These machines are equipped with 26″ **Wheels,** 2¼″ G & J tires, 20″ **Frame,** thus allowing the seat post to come in a line with top of frame. Color bright vermillion, option black or M. M. blue, **Full Nickled Rims,** producing the richest appearing Motor Cycle ever built.

Our Engine with its **Newly Designed Cylinder** developing more than 3 H. P., together with the splendid M. M. belt transmission using a 1¾″ wide, highest quality, **Barnes Endless Mineral Tan,** double thick, sewed belt, gives you more power, strength, stability, speed and endurance than any other single cylinder Motor Cycle in the World.

A New Battery Arrangement, New Idler Device for the Chain, with long rear adjusting slot, admitting of a longer range of adjustment, thereby taking up any slack that might appear in the belt, and doing away with the belt idler. **Belt Removable Through Rear Frame by Simply Removing One Bolt.**

We are equipping these machines with **Patent Motor Stand,** light, compact and built to the frame ready to hold your machine at a moment's notice.

On tank will be found a priming device in direct connection with the cupped petcock on cylinder head, thus admitting gasolene to cylinder for easy starting in cold weather by simply pressing a button.

These are only a few of the improved features found on the M. M. for 1908. *Write for our latest circular.*

Agents get busy—good territory still open.

American Motor Company

pring Handle Bar herewith shown. It is

The "C-A" Bar Attachment showing position of springs.

he product of the C-A Cycle Handle Bar Co., 1931 Broadway, New York City.

By means of this device the jolt and ar experienced in riding a stiff and rigid bar are said to be entirely absorbed. It can be attached to any make of machine using handle-bar steering not over 12 inches in length. Specially designed spring grips for bars over 12 inches in length can be furnished.

The "C-A" Spring Attachment with Bars Attached.

The C-A Spring Bar can be adjusted to any desired position, is provided with compression springs which are adjustable to any required tension, is free in action, and allows of very rigid steering. The price of the device polished and nickled is $6.00.

Atlantic City's Industrial Handicap Cycle Race

The successful 25-mile Industrial Handicap at Atlantic City, N. J., August 31. originally planned as a feature of the C. M. A. and the C. P. A. A. convention, was won by Philip Kury. Fifty-six of the sixty-nine starters finished. Preceding the race was a parade of over 100 bicyclists to the course. Results:

Place Winners.

1. Philip Kury, Roy W 1.13.23 4-5
2. Samuel Rein, Roy W 1.13.24
3. R. Nelson, Pleasantville 1.13.24 1-5

Time Winners.

1. C. A. Sherwood, N. Y. A. C. ..1.08.57 4-5
2. Chas. Mock, C. R. C. of A. .1.08.58
